THE
KHEJRI
CROPPING
SYSTEM

Khejri grows luxuriantly under the extremely adverse agroclimate in hot arid regions and that too without much cultural care. This leguminous species is compatible to almost all companion crops grown under the traditional cropping systems. It is a major source of leaf fodder (*loong*) and its immature pods (*sangri*) are used as vegetable, and the produce is nutritious and high valued. From a mature tree (20 years age), 25-30 kg leaves and 10-15 kg tender pods can be harvested annually. Khejri is a leguminous tree crop having multiple uses, viz. nutritious rich pods and fodder and even fuel, besides its favourable effects on ecology and soil fertility. It not only tolerates the extreme edapho-climatic conditions of *Thar Desert* but also have plentiful foliage, bears flowers and fruits and that too during the driest period. From wide genetic variability, some genotypes that produce high quality pods were collected for *ex situ* evaluation and conservation. From them, *Thar Shobha* is recommended to develop plantations for uniform *sangri* production. Tender pods (*sangri*) are sold at high cost both fresh and dehydrated (Rs. 160/kg and 300-500/kg, respectively) and is a eye-catching vegetable.

KHEJRI, *Prosopis cineraria*, is a multipurpose tree and lifeline of the Indian desert. There has been advancement made in bud grafting and dry sowing of variety. *Thar Shobha* in CTAHR, Bikaner, have resulted into wide spread popularization of this valuable tree. These technologies have been recommended for establishing plantations for uniform *sangri* production. Systematic production of standard product from such plantations would add value to the already existing biotic trade in dehydrated pods (*sangri*) and provide assured, sustained, better quality, higher returns and quantity produce to the people.

Varietal Development

Being cross-pollinated, considerable genetic variability does exist in the widespread seedling population of *Thar*. Wide range of variation are recorded in immature pod traits such as taste (bitter, acrid, sweet), tenderness (hard, semi-hard, less tender, tender), shape (round, flat, flat-round, oblique, wrinkled), fibre content (fibrous, less fibrous, fibreless), colour (green, light green, dark green) and length (10-30 mm) for horticultural exploitation. From the intensively studied seedlings showing variability, 15 genotypes were collected from 2002 for *ex situ* conservation. *Thar Shobha* was recommended in 1997 and popularized by orcharding.

Khejri seedling trunk for many budding or grafting.

Thar Shobha

It is a new variety of *Thar* grown and developed in Thar Desert. It is a selected clone of *Thar* with low seedling mortality and high yield. It is extremely耐旱 (drought resistant),耐热 (heat resistant),耐寒 (cold resistant),耐盐 (salt resistant),耐风沙 (wind resistant),耐病虫害 (resistant to pests and diseases). It is a good producer of tender pods (*sangri*). Its pods are round, hard, and have high protein content. The seeds are large and have high oil content. The tree is tall and has a dense canopy. The bark is smooth and greyish brown. The leaves are compound and pinnate. The flowers are small and yellow. The fruit is a pod containing several seeds. The tree is well suited for arid regions and can withstand long periods of drought. It is a good source of protein and oil for humans and animals. It is also used as a source of fiber for textiles and paper.

Intercropping of cluster bean in wider spaced khejri planting model (BS = 1.5 x 4 m) under rainfed conditions

Development of Khejri Based Production Sites

The traditional and farming systems have provided sustenance to the desert dwellers. In vast arid farm lands, cultivation of pearl millet, cluster bean, moth bean, sesame and cucurbits is done between the natural plantations of khejri as component crops, and in addition some native trees/shrubs grasses jharber, bordi, lasora, pila, ker, phog, sewan, etc. are the part of traditional agro-horti-silvi pastoral system prevalent under rainfed situations in the hot arid region of India. This system of harvesting of agriculture produce can provide sound farm economy, improved nutrition and health standards of the livelihood and stability when there is a good monsoon rains during the khari season. However under the changed scenario, the focus has shifted from sustenance to remunerative farming. But mono cropping is much risky for the development of desert horticulture due to scanty, uneven and failure of monsoon rains. Therefore, the traditional farming systems of arid region predominantly mixed cropping needs multi dimensional exploitation through interventions between native crop species and other endogenous arrangements. Now this can potentially be exploited under the concept "Horticultural Based Production Site Management Approach (HBCPSMA)".

Based on Silviculture for desert horticulture, some principles of site selection, community based

Tender pods of khejri variety Thar Sivalik for vegetable use as sangri

concept HBCPSMA for site development and management of production sites. The production sites should be developed in association with the topography, soil and dune land features and soil conditions. Fencing of production sites and development of multi-tier rows of seedling plantations of native species such as khejri, lasora, rohida and bordi with desert shrub floras all around the clock fencing has been taken in to consideration for the creation of favourable microclimate and protection of production site, and fallow fields from April to June or October November for soil health development and security are the prime. Pre monsoon field ploughing during June prior to rainy season crop sowing and post monsoon field ploughing during November after harvesting results in more *in situ* rain water harvesting, moisture conservation and weed free field in the production site. Besides, seed selection, sowing time and techniques, maintenance of plant population and crop protection measures are good management practices for intercropping crops.

Based on Silviculture for desert horticulture, some principles of site selection, community based
