ICAR - NATIONAL BUREAU OF SOIL SURVEY AND LAND USE PLANNING

About ICAR - NBSS&LUP

The ICAR-National Bureau of Soil Survey and Land Use Planning (ICAR-NBSS&LUP), Nagpur, a premier Institute of the Indian Council of Agricultural Research (ICAR), was set up during 1976 with the objective to prepare soil resource maps at national, state and district levels and to provide research inputs in soil resource mapping and its applications, land evaluation, land use planning, land resource management, and database management using GIS for optimising land use on different kinds of soils in the country.

The Bureau has been engaged in carrying out soil resource survey, agro-ecological and soil degradation mapping at the country, state and district levels for qualitative assessment and monitoring the soil health towards viable land use planning. The research activities have resulted in identifying the soil potentials and problems, and the various applications of the soil surveys with the ultimate objective of sustainable agricultural development. The Bureau has the mandate to correlate and classify soils of the country and maintain a National Register of all the established soil series. The Institute is also imparting in-service training to staff of the soil survey agencies in the area of soil survey, land evaluation and soil survey interpretations for land use planning. The Bureau in collaboration with Panjabrao Krishi Vidyapeeth, Akola is running post-graduate teaching and research programme in land resource management, leading to M.Sc. and Ph.D. degrees.

WATERSHED DEVELOPMENT DEPARTMENT, GOVT. OF KARNATAKA, BANGALORE

PREFACE

In Karnataka, as in other Indian States, the livelihoods of rural people are intertwined with farming pursuits. The challenges in agriculture are seriously threatening the livelihood of a large number of farmers as they have been practicing farming in contextual factors beyond their control. Climatic factors are the most important ones and have become much more significant in recent times due to rapid climate changes induced by intensive anthropogenic activities affecting our ecosystem in multiple ways. Climate change has become the reality, it is happening and efforts to evolve and demonstrate climate resilient technologies have become essential. Due to the already over stressed scenario of agrarian sector, the climate change is resulting in manifold increase in the complexities, pushing the rural mass to face more and more unpredictable situations. The rising temperatures and unpredictable rainfall patterns are going to test seriously the informed decisions farmers have to make in order to survive in farming and sustain their livelihood.

It is generally recognized that impacts of climate change shall not be uniform across the globe. It is said that impact of climate change is more severe in South Asia. Based on the analysis of meteorological data, it is predicted that in India, there will be upward trend in mean temperature, downward trend in relative humidity, annual rainfall and number of wet days in a year. Also, in general, phenomena like erratic monsoon, spread of tropical diseases, rise in sea levels, changes in availability of fresh water, frequent floods, droughts, heat waves, storms and hurricanes are predicted. Each one of these adverse situations are already being experienced in various parts of India and also at the global level. Decline in agricultural productivity of small and marginal farmers becoming more vulnerable is already witnessed.

In Karnataka, more than 60 per cent of the population live in rural areas and depend on agriculture and allied activities for their livelihood. Though the state has achieved significant progress in increasing the yield of many crops, there is tremendous pressure on the land resources due to the growing and competing demands of various land uses. This is reflected in the alarming rate of land degradation observed. Already more than 50 per cent of the area is affected by various forms of degradation. If this trend continues, the sustainability of the fragile ecosystem will be badly affected. The adverse effects of change in the climatic factors are putting additional stress on the land resources and the farmers dependent on this.

The natural resources (land, water and vegetation) of the state need adequate and constant care and management, backed by site-specific technological interventions and investments particularly by the government. Detailed database pertaining to the nature of

the land resources, their constraints, inherent potentials and suitability for various land based rural enterprises, crops and other uses is a prerequisite for preparing location-specific action plans, which are in tune with the inherent capability of the resources. Any effort to evolve climate resilient technologies has to be based on the baseline scientific database. Then only one can expect effective implementation of climate resilient technologies, monitor the progress, make essential review of the strategy, and finally evaluate the effectiveness of the implemented programs. The information available at present on the land resources of the state are of general nature and useful only for general purpose planning. Since the need of the hour is to have site-specific information suitable for farm level planning and detailed characterization and delineation of the existing land resources of an area into similar management units is the only option.

ICAR-NBSS&LUP, Regional Centre, Bangalore has taken up a project sponsored by the Karnataka Watershed Development Project-II, (Sujala-III), Government of Karnataka funded by the World Bank under Component -1 Land Resource Inventry. This study was taken up to demonstrate the utility of such a database in reviewing, monitoring and evaluating all the land based watershed development programs on a scientific footing. To meet the requirements of various land use planners at grassroots level, the present study on "Land Resource Inventory and Socio-Economic Status of Farm Households for Watershed Planning and Development of for Adavalli-4 microwatershed in Koppal Taluk and District, Karnataka" for integrated development was taken up in collaboration with the State Agricutural Universities, IISC, KSRSAC, KSNDMC as Consortia partners. The project provides detailed land resource information at cadastral level (1:7920 scale) for all the plots and socio-economic status of farm households covering thirty per cent farmers randomely selected representing landed and landless class of farmers in the microwatershed. The project report with the accompanying maps for the microwatershed will provide required detailed database for evolving effective land use plan, alternative land use options and conservation plans for the planners, administrators, agricutural extention personnel, KVK officials, developmental departments and other land users to manage the land resources in a sustainable manner.

It is hoped that this database will be useful to the planners, administrators and developmental agencies working in the area in not only for formulating location specific developmental schemes but also for their effective monitoring at the village/watershed level.

EXECUTIVE SUMMARY

The land resource inventory of Adavalli-4 microwatershed was conducted using village cadastral maps and IRS satellite imagery on 1:7920 scale. The false colour composites of IRS imagery were interpreted for physiography and these physiographic delineations were used as base for mapping soils. The soils were studied in several transects and a soil map was prepared with phases of soil series as mapping units. Random checks were made all over the area outside the transects to confirm and validate the soil map unit boundaries. The soil map shows the geographic distribution and extent, characteristics, classification, behaviour and use potentials of the soils in the microwatershed.

The present study covers an area of 474 ha in Koppal taluk and district, Karnataka. The climate is semiarid and categorized as drought - prone with an average annual rainfall of 662 mm, of which about 424 mm is received during south –west monsoon, 161 mm during north-east and the remaining 77 mm during the rest of the year. An area of about 98 per cent is covered by soils, two per cent by water bodies, settlements and others. The salient findings from the land resource inventory are summarized briefly below.

- ❖ The soils belong to 8 soil series and 11 soil phases (management units) and 5 land use classes.
- * The length of crop growing period is <90 days and starts from 2^{nd} week of August to 2^{nd} week of November.
- ❖ From the master soil map, several interpretative and thematic maps like land capability, soil depth, surface soil texture, soil gravelliness, available water capacity, soil slope and soil erosion were generated.
- Soil fertility status maps for macro and micronutrients were generated based on the surface soil samples collected at every 250 m grid interval.
- Land suitability for growing 24 major agricultural and horticultural crops were assessed and maps showing the degree of suitability along with constraints were generated.
- ***** *Entire area is suitable for agriculture.*
- ❖ About 27 per cent of the soils are shallow to very shallow (<25 cm) to moderately shallow (50-75 cm) and about 70 per cent are moderately deep to very deep soils (75->150 cm).
- **the surface.** Entire area has clayey soils at the surface.
- ❖ About 70 per cent of the area has non-gravelly soils, 26 per cent gravelly soils (15-35 % gravel) and 2 per cent extremely gravelly (60-80% gravel) soils.
- ❖ About 27 per cent of the area has very low (<50mm/m) to low (51-100 mm/m), 41 per cent medium (101-150 mm/m) and 29 per cent area very high (>200mm/m) available water capacity.
- ❖ Entire area has very gently sloping (1-3%) lands.

- ❖ Entire area has moderately eroded (e2) lands.
- ❖ An area of about 28 per cent has soils that are strongly alkaline (pH 8.4-9.0) and 69 per cent very strongly alkaline (pH>9.0).
- ❖ The Electrical Conductivity (EC) of the soils are dominantly <2 dsm⁻¹indicating that the soils are non-saline.
- ❖ Organic carbon is low (<0.5%) in about 34 per cent, 39 per cent of the soils are medium (0.5-0.75%) and 25 per cent of the soils are high (>0.75%) in organic carbon.
- ❖ Available phosphorus is low (<23 kg/ha) in about 96 per cent and medium (23-57 kg/ha) is 2 per cent area of the microwatershed.
- ❖ Available potassium is medium (145-337 kg/ha) in entire microwatershed area.
- ❖ Available sulphur is low (<10 ppm) in 60 per cent area, medium (10-20 ppm) in about <1 per cent area and about 37 per cent area is high (>10 ppm).
- Available boron is low (0.5 ppm) in about 56 per cent area, medium (0.5-1.0 ppm) in 2 per cent and 40 per cent is high (>1.0 ppm).
- ❖ Available iron is sufficient (>4.5 ppm) in the entire area.
- \diamond Available zinc is deficient (<0.6 ppm) in the entire area.
- ❖ Available manganese and copper are sufficient in all the soils.
- ❖ The land suitability for 24 major crops grown in the microwatershed was assessed and the areas that are highly suitable (S1) and moderately suitable (S2) are given below. It is however to be noted that a given soil may be suitable for various crops but what specific crop to be grown may be decided by the farmer looking to his capacity to invest on various inputs, marketing infrastructure, market price, price and finally the demand and supply position.

Land suitability for various crops in the microwatershed

	Suitability Area in ha (%)			Suitability Area in ha (%)	
Crop	Highly suitable (S1)	Moderately suitable (S2)	Стор	Highly suitable (S1)	Moderately suitable (S2)
Sorghum	260 (55)	91 (19)	Sapota	-	-
Maize	-	-	Jackfruit	-	-
Bajra	-	-	Jamun	-	139 (29)
Groundnut	-	26 (6)	Musambi	139 (29)	187 (39)
Sunflower	139 (29)	187 (39)	Lime	139 (29)	187 (39)
Chilli	-	-	Cashew	-	-
Tomato	-	-	Custard apple	260 (55)	91 (19)
Drumstick	-	326 (69)	Amla	-	351 (74)
Mulbery		351 (74)	Tamarind	-	139 (29)
Pomegranate	-	326 (69)	Marigold	-	351 (74)
Guava	-	-	Chrysanthemum	-	351 (74)
Mango	-	-	Jasmine	-	26 (6)

Apart from the individual crop suitability, a proposed crop plan has been prepared for the 5 identified LUCs by considering only the highly and moderately suitable lands for different crops and cropping systems with food, fodder, fibre and other horticulture crops.

- * Maintaining soil-health is vital to crop production and conserve soil and land resource base for maintaining ecological balance and to mitigate climate change. For this, several ameliorative measures have been suggested to these problematic soils like saline/alkali, highly eroded, sandy soils etc.,
- Soil and water conservation treatment plan has been prepared that would help in identifying the sites to be treated and also the type of structures required.
- As part of the greening programme, several tree species have been suggested to be planted in marginal and submarginal lands, field bunds and also in the hillocks, mounds and ridges. That would help in supplementing the farm income, provide fodder and fuel, and generate lot of biomass which inturn would help in maintaining the ecological balance and contributes to mitigating the climate change.

INTRODUCTION

Land is a scarce resource and basic unit for any material production. It can support the needs of the growing population, provided they use the land in a rational and judicious manner. But what is happening in many areas of the state is a cause for concern to everyone involved in the management of land resources at the grassroots level. The area available for agriculture is about 51 per cent of the total area and more than 60 per cent of the people are still dependant on agriculture for their livelihood. The limited land area is under severe stress and strain due to increasing population pressure and competing demands of various land uses. Due to this, every year there is significant diversion of farm lands and water resources for non-agricultural purposes. Apart from this, due to lack of interest in farmers for farming, large tracts of cultivable lands are turning into fallows in many areas and this trend is continuing at an alarming rate.

Further, land degradation has emerged as a serious problem which has already affected about 38 lakh ha of cultivated area in the state. Soil erosion alone has degraded about 35 lakh ha. Almost all the uncultivated areas are facing various degrees of degradation, particularly soil erosion. Salinity and alkalinity has emerged as a major problem in more than 3.5 lakh ha in the irrigated areas of the state. Nutrient depletion and declining factor productivity is common in both rainfed and irrigated areas. The degradation is continuing at an alarming rate and there appears to be no systematic effort among the stakeholders to contain this process. In recent times, an aberration of weather due to climate change phenomenon has added another dimension leading to unpredictable situations to be tackled by the farmers.

In this critical juncture, the challenge before us is not only to increase the productivity per unit area which is steadily declining and showing a fatigue syndrome, but also to prevent or at least reduce the severity of degradation. If the situation is not reversed at the earliest, then the sustainability of the already fragile crop production system and the overall ecosystem will be badly affected in the state.

The continued neglect and unscientific use of the resources for a long time has led to the situation observed at present in the state. It is a known fact and established beyond doubt by many studies in the past that the cause for all kinds of degradation is the neglect and irrational use of the land resources. Hence, there is urgent need to generate a detailed site-specific farm level database on various land resources for all the villages/watersheds in a time bound manner that would help to protect the valuable soil and land resources and also to stabilize the farm production.

Therefore, the land resource inventory required for farm level planning is the one which investigates not only the surface but also consider the other parameters which are critical for productivity *viz.*, soils, climate, water, minerals and rocks, topography, geology, hydrology, vegetation, crops, land use pattern, animal population, socioeconomic conditions, infrastructure, marketing facilities and various schemes and

developmental works of the government etc. From the data collected at farm level, the specific problems and potentials of the area can be identified and highlighted, conservation measures required for the area can be planned on a scientific footing, suitability of the area for various uses can be worked out and finally viable and sustainable land use options suitable for each and every land holding can be prescribed.

The Land Resource Inventory is basically done for identifying potential and problem areas, developing sustainable land use plans, estimation of surface run off and water harvesting potential, preparation of soil and water conservation plans, land degradation/desertification etc. The Bureau is presently engaged in developing an LRI methodology using high resolution satellite remote sensing data and Digital Elevation Model (DEM) data to prepare Landscape Ecological Units (LEU) map representing agroecosystem as a whole. The LEU is preferred over landform as the base map for LRI. LEU is the assemblage of landform, slope and land use. An attempt was made to upscale the soil resource information from 1:250000 and 1:50000 scale to the LEU map in Goa and other states.

The land resource inventory aims to provide site specific database for Adavalli-4 microwatershed in Koppal Taluk, Koppal District, Karnataka State for the Karnataka Watershed Development Department. The database was generated by using cadastral map of the village as a base along with high resolution IRS LISS IV and Cartosat-1 merged satellite imagery. Later, an attempt will be made to uplink this LRI data generated at 1:7920 scale under Sujala-III Project to the proposed Landscape Ecological Units (LEUs) map.

The study was organized and executed by the ICAR- National Bureau of Soil Survey and Land Use Planning, Regional Centre, Bangalore under Generation of Land Resource Inventory Data Base Component-1 of the Sujala-III Project funded by the World Bank.

GEOGRAPHICAL SETTING

2.1 Location and Extent

The Adavalli-4 Microwatershed is located in the central part of northern Karnataka in Koppal Taluk, Koppal District, Karnataka State (Fig.2.1). It comprises parts of Kavalura village. It lies between 15⁰ 19' and 15⁰ 21' North latitudes and 75⁰ 55' and 75⁰ 57' East longitudes and covers an area of 474 ha. It is about 70 km from Koppal town and is surrounded by Kavalura village on the western, northern and southern part and Yelburga taluk on the eastern part of the microwatershed.

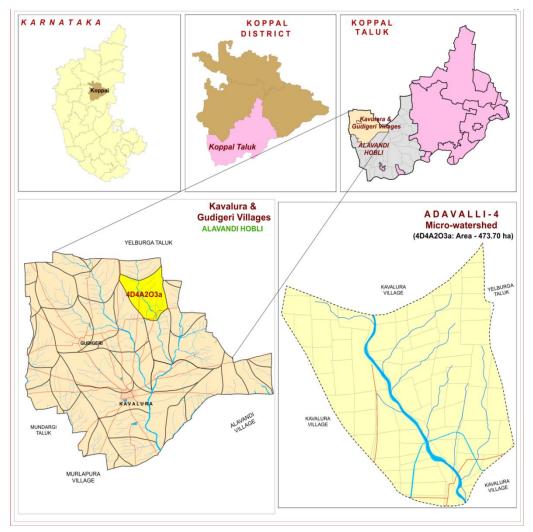

Fig.2.1 Location map of Adavalli-4 Microwatershed

2.2 Geology

Major rock formations observed in the microwatershed are granite gneiss and alluvium (Figs.2.2a and b). Granite gneisses are essentially pink to gray and are coarse to medium grained. They consist primarily of quartz, feldspar, biotite and hornblende. The gray granite gneisses are highly weathered, fractured and fissured upto a depth of about 10 m. Dolerite dykes and quartz veins are common with variable width and found to

occur in Adavalli-4 village. The soil thickness of the alluvium generally is limited to less than a meter, except in river valleys where it is very deep extending to tens of meters. Such soils are transported and represent palaeo black soil originally formed at higher elevation, but now occupying river valleys.

Fig.2.2 Granite and granite gneiss rocks

Fig.2.2 b Alluvium

2.3 Physiography

Physiographically, the area has been identified as Granite gneiss and Alluvial landscapes based on geology. The microwatershed area has been further divided into mounds/ridges, summits, side slopes and very gently sloping uplands and nearly level plains based on slope and its relief features. The elevation ranges from 540 to 566 m in the gently sloping uplands. The mounds and ridges are mostly covered by rock outcrops.

2.4 Drainage

The area is drained by several small seasonal streams that join Hire *halla* and Chenna *halla* along its course. Though, the streams are not perennial, during rainy season they carry large quantities of rain water. The microwatershed has only few small tanks which are not able to store the water flowing during the rainy season. Due to this, the

ground water recharge is very much affected in the villages. This is reflected in the failure of many bore wells in the villages. If the available rain water is properly harnessed by constructing tanks and recharge structures at appropriate places in the villages, then the drinking and irrigation needs of the area can be easily met. The drainage network is dendritic to sub parallel.

2.5 Climate

The district falls under semiarid tract of the state and is categorized as drought - prone with total annual rainfall of 662 mm (Table 2.1). Maximum of 424 mm precipitation takes place during south—west monsoon period from June to September, north-east monsoon contributes about 161 mm and prevails from October to early December and the remaining 77 mm takes place during the rest of the year.

Table 2.1 Mean Monthly Rainfall, PET, 1/2 PET at Koppal Taluk and District

Sl.No.	Months	Rainfall	PET	1/2 PET
1	January	1.60	116.70	58.35
2	February	1.50	129.20	64.60
3	March	14.10	169.80	84.90
4	April	18.10	180.60	90.30
5	May	41.60	193.50	96.75
6	June	85.80	167.90	83.95
7	July	72.10	156.20	78.10
8	August	110.50	152.50	76.25
9	September	155.60	138.50	69.25
10	October	116.30	122.30	61.15
11	November	36.00	106.40	53.20
12	December	9.10	101.00	50.50
	TOTAL	662.30	144.55	

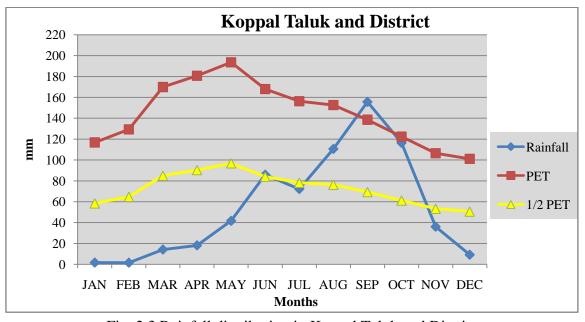

Fig. 2.3 Rainfall distribution in Koppal Taluk and District

The winter season is from December to February. During April and May, the temperatures reach up to 45° C and in December and January, the temperatures will go down to 16° C. Rainfall distribution is shown in Figure 2.3. The average Potential Evapo Transpiration (PET) is 145 mm and varies from a low of 101 mm in December and 193 mm in the months of May. The PET is always higher than precipitation in all the months except in the month of September. Generally, the Length of crop Growing Period (LGP) is <90 days and starts from 2^{nd} week of August to 2^{nd} week of November.

2.6 Natural Vegetation

The natural vegetation is sparse comprising few tree species, shrubs and herbs. The mounds, ridges and boulders occupy sizeable areas which are under thin to moderately thick forest vegetation. Still, there are some remnants of the past forest cover which can be seen in patches in some ridges and hillocks in the microwatershed Fig (2.4).

Apart from the continuing deforestation, the presence of large population of goats, sheep and other cattle in the microwatershed is causing vegetative degradation of whatever little vegetation left in the area. The uncontrolled grazing has left no time for the regeneration of the vegetative cover. This leads to the accelerated rate of erosion on the hill slopes, resulting in the formation of deep gullies in the foot slopes and eventually resulting in the heavy siltation of few tanks and reservoirs in the microwatershed.

Fig 2.4 Natural vegetation of Adavalli-4 microwatershed

2.7 Land Utilization

About 91 per cent area (Table 2.2) in Koppal district is cultivated at present and about 16 per cent of the area is sown more than once. An area of about 3 per cent is currently barren. Forests occupy a small area of about 5 per cent and the tree cover is in a very poor state. Most of the mounds, ridges and bouldery areas have very poor vegetative cover. Major crops grown in the area are Sorghum, Maize, Bajra, Cotton, Safflower, Sunflower, Red gram, Horse gram, Onion, Mulberry, Pomegranate, Sugarcane, Bengal gram and groundnut (Fig 2.6). While carrying out land resource inventory, the land

use/land cover particulars are collected from all the survey numbers and a current land use map of the microwatershed is prepared. The current land use map prepared shows the arable and non-arable lands, other land uses and different types of crops grown in the area. The current land use map of Adavalli-4 Microwatershed is presented in Fig.2.5. Simultaneously, enumeration of existing wells (bore wells and open wells) and other soil and water conservation structures in the microwatershed is made and their location in different survey numbers is marked on the cadastral map. Map showing the location of wells, soil conservation structures and other water bodies in Adavalli-4 Microwatershed is given Fig.2.7.

SURVEY METHODOLOGY

The purpose of land resource inventory is to delineate similar areas (soil series and phases), which respond or expected to respond similarly to a given level of management. This was achieved in Adavalli-4 Microwatershed by the detailed study of all the soil characteristics (depth, texture, colour, structure, consistence, coarse fragments, porosity, soil reaction, soil horizons etc.) and site (slope, erosion, drainage, occurrence of rock fragments etc.) and followed by grouping of similar areas based on soil-site characteristics into homogeneous (management units) units and showing their extent and geographic distribution on the microwatershed cadastral map. The detailed soil survey at 1:7920 scale was carried out in 474 ha area. The methodology followed for carrying out land resource inventory was as per the guidelines given in Soil Survey Manual (IARI, 1971; Soil Survey Staff, 2006; Natarajan *et al.*, 2015) which is briefly described below.

3.1 Base Maps

The detailed survey of the land resources occurring in the microwatershed was carried out by using digitized cadastral map as a base. The cadastral map shows field boundaries with their survey numbers, location of tanks, streams and other permanent features of the area (Fig. 3.1). Apart from the cadastral map, remote sensing data products from Cartosat-1 and LISS IV merged at the scale of 1:7920 were used in conjunction with the cadastral map to identify the geology, landscapes, landforms and other surface features. The imagery helped in the identification and delineation of boundaries between hills, uplands and lowlands, water bodies, forest and vegetated areas, roads, habitations and other cultural features of the area (Fig.3.2). The cadastral map was overlaid on the satellite imagery (Fig.3.3) that helps to identify the parcel boundaries and other permanent features. Apart from cadastral maps and images, toposheets of the area (1:50,000 scale) were used for initial traversing, identification of geology, landscapes and landforms, drainage features, present land use and also for selection of transects in the microwatershed.

3.2 Image Interpretation for Physiography

False Colour Composites (FCC) of Cartosat-I and LISS-IV merged satellite data covering the microwatershed area was visually interpreted using image interpretation elements and all the available collateral data with local knowledge. The delineated physiographic boundaries were transferred on to a cadastral map overlaid on satellite imagery. Physiographically, the area has been identified as granite gneiss and alluvial landscapes and is divided into landforms such as ridges, mounds and uplands based on slope. They were further subdivided into physiographic/ image interpretation units based on image characteristics. The image interpretation legend for physiography is given below.

Image Interpretation Legend for Physiography

3.3 Field Investigation

The field boundaries and survey numbers given on the cadastral sheet were located on the ground by following permanent features like roads, cart tracks, *nallas*, streams, tanks etc., and wherever changes were noticed, they were incorporated on the microwatershed cadastral map. Preliminary traverse of the microwatershed was carried out with the help of cadastral map, imagery and toposheets. While traversing, landforms and physiographic units identified were checked and preliminary soil legend was prepared by studying soils at few selected places. Then, intensive traversing of each physiographic unit like hills, ridges, uplands and plains was carried out. Based on the variability observed on the surface, transects (Fig 3.4) were selected across the slope covering all the landform units in the microwatershed (Natarajan & Dipak Sarkar, 2010).

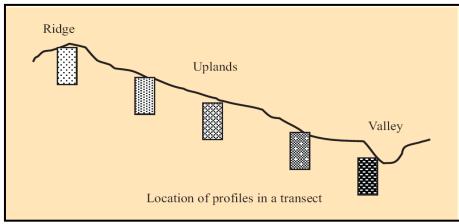

Fig: 3.4. Location of profiles in a transect

In the selected transect, soil profiles (Fig.3.4) were located at closely spaced intervals to take care of any change in the land features like break in slope, erosion, gravel, stones etc. In the selected sites, profiles (vertical cut showing the soil layers from surface to the rock) were opened up to 200 cm or to the depth limited by rock or hard substratum and studied in detail for all their morphological and physical characteristics. The soil and site characteristics were recorded for all profile sites on a standard proforma as per the guidelines given in USDA Soil Survey Manual (Soil Survey Staff, 2012). Apart from the transect study, profiles were also studied at random, almost like in a grid pattern, outside the transect areas to validate the soil map unit boundariers.

Based on the soil characteristics, the soils were grouped into different soil series. Soil series is the most homogeneous unit having similar horizons and properties and behaves similarly for a given level of management. Soil depth, texture, colour, kind of horizon and horizon sequence, amount and nature of gravel present, calcareousness, nature of substratum etc, were used as the major differentiating characteristics for identifying soil series occurring in the area. The differentiating characteristics used for identifying the soil series are given in Table 3.1. Based on the above characteristics, 8 soil series were identified in Adavalli-4 Microwatershed.

Table 3.1 Differentiating Characteristics used for identifying Soil Series (Characteristics are of Series Control Section)

(Characteristics are of Series Control Section)

8	Bardur (BDR)	>150	10 YR2/1, 3/1, 3/2	С	<15	Ap-Bss	es

3.4 Soil Mapping

The area under each soil series was further separated into soil phases and their boundaries delineated on the cadastral map based on the variations observed in the texture of the surface soil, slope, erosion, presence of gravel, stoniness etc. A soil phase is a subdivision of soil series based mostly on surface features that affect its use and management. The soil mapping units are shown on the map (Fig.3.5) in the form of symbols. During the survey many soil profile pits, few minipits and a few auger bores representing different landforms occurring in the microwatershed were studied. In addition to the profile study, spot observations in the form of minipits, road cuts, terrace cuts etc., were studied to validate the soil boundaries on the soil map. The soil map shows the geographic distribution of 11 mapping units representing 8 soil series occurring in the microwatershed. The soil map unit (soil legend) description is presented in Table 3.2. The soil phase map (management units) shows the distribution of 11 phases mapped in the microwatershed. Each mapping unit (soil phase) delineated on the map has similar soil and site characteristics. In other words, all the farms or survey numbers included in one phase will have similar management needs and have to be treated accordingly.

3.5 Laboratory Characterization

Soil samples for each series were collected from representative master profiles for laboratory characterization by following the methods outlined in the Laboratory Manual (Sarma *et al*, 1987). Surface soil samples collected in the year 2017 from Adavalli-4 farmer's fields (47 samples) for fertility status (major and micronutrients) at 250 m grid interval were analyzed in the laboratory (Katyal and Rattan, 2003). By linking the soil fertility data to the survey numbers through GIS, soil fertility maps were generated using Kriging method for the microwatershed.

3.6 Land Use Classes

The 11 soil phases identified and mapped in the microwatershed were regrouped into 5 Land Use Classes (LUC's) for the purpose of preparing a Proposed Crop Plan for sustained development of the microwatershed. The database (soil phases) generated under LRI was utilized for identifying Land Use Classes (LUC's) based on the management needs. One or more than one soil site characteristic having influence on the management have been choosen for identification and delineation of LUCs. For Adavalli-4 Microwatershed, five soil and site characteristics, namely soil depth, soil texture, slope erosion and gravel content have been considered for defining LUCs. The land use classes are expected to behave similarly for a given level of management.

THE SOILS

Detailed information pertaining to the nature, extent and distribution of different kinds of soils occurring in Adavalli-4 Microwatershed is provided in this chapter. The microwatershed area has been identified as Granite gneiss and Alluvium Landscapes based on geology. In all, 8 soil series are identified. Soil formation is the result of the combined effect of environmental and terrain factors that are reflected in soil morphology. The soil formation is dominantly influenced by the parent material, climate and relief.

A brief description of each of the 8 soil series identified followed by 11 soil phases (management units) mapped under each series (Fig. 3.4) are furnished below. The physical and chemical characteristics of soil series identified in Adavalli-4 microwatershed are given in Table 4.1. The soils in any one map unit differ from place to place in their depth, texture, slope, gravelliness, erosion or any other site characteristic that affect management. The soil phase map can be used for identifying the suitability of areas for growing specific crops or for other alternative uses and also for deciding the type of conservation structures needed. The detailed information on soil and site-characteristics like soil depth, surface soil texture, slope, erosion, gravelliness, AWC, LCC etc, with respect to each of the soil phase identified is given village/survey number wise for the microwatershed in Appendix-I.

4.1 Soils of Granite and Granite gneiss landscape

In this landscape, only one soil series is identified and mapped. The brief description of each soil series and one soil phase identified in the microwatershed are given below.

4.1.1 Belagatti (BGT) Series: Belagatti soils are very shallow (< 25 cm), well drained, have dark gray to dark grayish brown gravelly clay soils. They have developed from granite gneiss and occur on very gently sloping uplands. Belagatti series has been classified as a member of the clayey mixed, isohyperthermic family of Lithic Ustorthents.

Landscape and soil profile characteristics of Belagatti (BGT) Series

The thickness of the soil is less than 25 cm. Its colour is in 10 YR hue with value 3 to 4 and chroma 1 to 2. The texture is clay with more than 35 per cent gravel and the available water capacity is low (51-100 mm/m). Only one soil phase was identified and mapped

4.2 Soils of Alluvial Landscape

In this landscape, 7 soil series are identified and mapped. Of these, Narsapura (NSP) series occupies maximum area of 129 ha (27%) and Muttal (MTL) of 103 ha (22%) The brief description of each soil series along with the soil phases identified and mapped is given below.

4.2.1 Muttal (MTL) Series: Muttal soils are shallow (25-50 cm), well drained, have dark brown to very dark grayish brown, calcareous gravelly clay soils. They have developed from alluvium and occur on nearly level to very gently sloping uplands. The Muttal series has been classified as a member of the clayey, mixed, isohyperthermic (Calc) family of (Paralithic) Haplustepts.

The thickness of the solum ranges from 30 to 50 cm. The thickness of A horizon ranges from 15 to 18 cm. Its colour is in 7.5 YR and 10 YR hue with value 2 to 3 and chroma 2.5 to 4. The texture varies from sandy clay to clay with 10 to 15 per cent gravel. The thickness of B horizon ranges from 18 to 32 cm. Its colour is in 10 YR and 7.5 YR hue with value 2 to 6 and chroma 2 to 4. Its texture is sandy clay to clay. The available water capacity is low (51-100 mm/m). Only one series was identified and mapped.

Landscape and soil profile characteristics of Muttal (MTL) Series

4.2.2 Ravanaki (**RNK**) **Series** Ravanaki soils are moderately shallow (50-75 cm), well drained, have dark brown to very dark grayish brown, calcareous clay soils. They have developed from alluvium and occur on nearly level to very gently sloping uplands. The Ravanaki series has been classified as a member of the very fine, smectitic, isohyperthermic (Calc) family of Typic Haplustepts.

The thickness of the solum ranges from 50 to 75 cm. The thickness of A horizon ranges from 15 to 20 cm. Its colour is in 7.5 YR and 10 YR hue with value 2 to 3 and

chroma 2.5 to 4. The texture varies from sandy clay to clay with 10 to 15 per cent gravel. The thickness of B horizon ranges from 35 to 60 cm. Its colour is in 10 YR and 7.5 YR hue with value 2 to 6 and chroma 2 to 4. Its texture is sandy clay to clay with gravel content of 10 to 20 per cent. The available water capacity is low (51-100 mm/m). Two phases were identified and mapped.

Landscape and Soil Profile Characteristics of Ravanaki (RNK) Series

4.2.3 Dambarahalli (DRL) Series: Dambarahalli soils are moderately deep (75-100 cm), moderately well drained, have black and very dark gray to dark brown calcareous cracking clay soils. They have developed from alluvium and occur on very gently to gently sloping uplands under cultivation.

The thickness of the solum ranges from 75 to 99 cm. The thickness of A horizon ranges from 13 to 24 cm. Its colour is in 10 YR hue with value 3 to 4 and chroma 1 to 2. The texture is clay. The thickness of B horizon ranges from 54 to 85 cm. Its colour is in 10 YR hue with value 2 to 4 and chroma 1 to 3. Its texture is clay and is calcareous. The available water capacity is high (150-200 mm/m). Only one soil phase identified and mapped.

Landscape and soil profile characteristics of Dambarahalli (DRL) Series.

4.2.4 Narasapura (**NSP**) **Series:** Narasapura soils are moderately deep (75-100 cm), moderately well drained, have dark grayish brown to very dark grayish brown and very dark gray, black cracking calcareous clay soils They have developed from alluvium and occur on very gently sloping uplands. The Narsapura series has been classified as a member of the Very fine, Smectitic, isohyperthermic (Calc) family of Typic Haplustepts.

The thickness of the solum is 76 to 98 cm. The thickness of A horizon ranges from 15 to 19 cm. Its colour is in 10 YR hue with value 3 and chroma 1 to 2. The texture is clay with no gravel. The thickness of B horizon ranges from 57 to 83 cm. Its colour is in 10 YR hue with value 3 to 5 and chroma 1 to 3. Its texture is clay. The available water capacity is medium (101-150 mm/m). Two soil phases identified and mapped.

Landscape and soil profile characteristics of Narsapura (NSP) series

4.2.5 Handrala (HDL) Series: Handrala soils are deep (100-150 cm), moderately well drained, have black, very dark brown to dark gray cracking clay soils. They are developed from alluvium and occur on very gently to gently sloping uplands. Handrala series has been classified as a member of the very fine, smectitic, isohyperthermic, (Calc) family of Typic Haplusterts.

Landscape and soil profile characteristics of Handrala (HDL) Series

The thickness of the solum ranges from 102 to 149 cm. The thickness of A horizon ranges from 14 to 26 cm. Its colour is in 10 YR hue with value 3 and chroma 1. The texture is clay. The thickness of B horizon ranges from 103 to 127 cm. Its colour is in 10 YR hue with value 2 to 4 and chroma 1 to 2. Texture is dominantly clay. The available water capacity is very high (>200 mm/m). Only one soil phase identified and mapped.

4.2.6 Kadagathur (KDT) Series: Kadagathur soils are very deep (>150 cm), moderately well drained, have dark brown to very dark grayish brown sandy clay to clay soils. They have developed from alluvium and occur on nearly level to very gently sloping uplands under cultivation.

The thickness of the solum is more than 150 cm. The thickness of A horizon ranges from 8 to 14 cm. Its colour is in 10 YR hue with value 3 and chroma 4. The texture varies from sandy loam to sandy clay and clay. The thickness of B horizon is more than 150 cm. Its colour is 10 YR and 7.5 YR hue with value 3 and chroma 1 to 4. Its texture is sandy clay to clay. The available water capacity is very high (>200 mm/m). Two soil phases identified and mapped.

Landscape and soil profile characteristics of Kadagathur (KDT) Series

4.2.7 Bardur (BDR) Series: Bardur soils are very deep (>150 cm), moderately well drained, have very dark grayish brown to very dark gray, black cracking calacreous clay soils. They have developed from alluvium and occur on nearly level to very gently sloping uplands under cultivation. Bardur series has been classified as member of the very fine, Smectitic, isohyperthermic (calc) family of Typic Haplusterts.

The thickness of the solum is more than 150 cm. The thickness of A horizon ranges from 15 to 19 cm. Its colour is in 10 YR hue with value 2 and chroma 1 with clay texture. The thickness of B horizon ranges from 146 to 180 cm. Its colour is in 10 YR hue with value 2 to 3 and chroma 1 to 2. Its texture is clay with less than 15 per cent gravel. The available water capacity is very high (>200 mm/m). Only one soil phase was identified and mapped.

Landscape and soil profile characteristics of Bardur (BDR) Series

INTERPRETATION FOR LAND RESOURCE MANAGEMENT

The most important soil and site characteristics that affect the land use and conservation needs of an area are land capability, soil depth, soil texture, coarse fragments, available water capacity, soil slope, soil erosion, soil reaction etc. These are interpreted from the data base generated through land resource inventory and several thematic maps are generated. These would help in identifying the areas suitable for growing crops and, soil and water conservation measures and structures needed thus helping to maintain good soil health for sustained crop production. The various thematic maps generated are described below.

5.1 Land Capability Classification

Land capability classification is an interpretative grouping of soil map units (soil phases) mainly based on inherent soil characteristics, external land features and environmental factors that limit the use of land for agriculture, pasture, forestry, or other uses on a sustained basis (IARI, 1971). The land and soil characteristics used to group the land resources in an area into various land capability classes, subclasses and units are *Soil characteristics*: Soil depth, soil texture, coarse fragments, soil reaction, available water capacity, calcareousness, salinity/alkali *etc*.

Land characteristics: Slope, erosion, drainage, rock outcrops.

Climate: Total rainfall and its distribution, and length of crop growing period.

The Land Capability Classification system is divided into land capability classes, subclasses and units based on the level of information available. Eight land capability classes are recognized. They are

- Class I: They are very good lands that have no limitations or very few limitations that restrict their use.
- Class II: They are good lands that have minor limitations and require moderate conservation practices.
- Class III: They are moderately good lands that have severe limitations that reduce the choice of crops or that require special conservation practices.
- Class IV: They are fairly good lands that have very severe limitations that reduce the choice of crops or that require very careful management.
- Class V: Soils in these lands are not likely to erode, but have other limitations like wetness that are impractical to remove and as such not suitable for agriculture, but suitable for pasture or forestry with minor limitations.
- Class VI: The lands have severe limitations that make them generally unsuitable for cultivation, but suitable for pasture or forestry with moderate limitations.
- Class VII: The lands have very severe limitations that make them unsuitable for cultivation, but suitable for pasture or forestry with major limitations.
- Class VIII: Soil and other miscellaneous areas (rock lands) that have very severe limitations that nearly preclude their use for any crop production, but suitable for wildlife, recreation and installation of wind mills.

The land capability subclasses are recognised based on the dominant limitations observed within a given land capability class. The subclasses are designated by adding a lower case letter like 'e', 'w', 's', or 'c' to the class numeral. The subclass "e" indicates that the main hazard is risk of erosion, "w" indicates drainage or wetness as a limitation for plant growth, "s" indicates shallow soil depth, coarse or heavy textures, calcareousness, salinity/alkalinity or gravelliness and "c" indicates limitation due to climate.

The land capability subclasses have been further subdivided into land capability units based on the kinds of limitations present in each subclass. Ten land capability units are used in grouping the soil map units. They are stony or rocky (0), erosion hazard (slope, erosion) (1), coarse texture (sand, loamy sand, sandy loam) (2), fine texture (cracking clay, silty clay) (3), slowly permeable subsoil (4), coarse underlying material (5), salinity/alkali (6), stagnation, overflow, high ground water table (7), soil depth (8) and fertility problems (9). The capability units thus identified have similar soil and land characteristics that respond similarly to a given level of management. The soils of the microwatershed have been classified upto land capability subclass level.

The 11 soil map units identified in the Adavalli-4 microwatershed are grouped under two land capability classes and three land capability subclasses (Fig. 5.1).

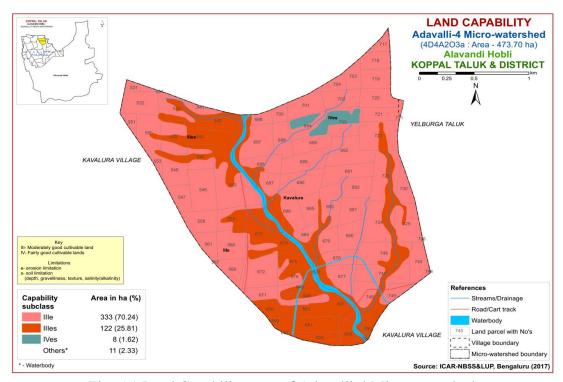

Fig. 5.1 Land Capability map of Adavalli-4 Microwatershed

Entire area is suitable for agriculture. Moderately good cultivable lands (Class III) cover an area of about 96 per cent and are distributed in all parts of the microwatershed with moderate problems of erosion and soil. Fairly good lands (Class IV) cover an area of

2 per cent and are distributed in the central part of the microwatershed with very severe limitations of soil and erosion.

5.2 Soil Depth

Soil depth refers to the depth of the soil occurring above the parent material or hard rock. The depth of the soil determines the effective rooting depth for plants and in accordance with soil texture, mineralogy and gravel content, the capacity of the soil column to hold water and nutrient availability. Soil depth is one of the most important soil characteristic that is used in differentiating soils into different soil series. The soil depth classes used in identifying soils in the field are very shallow (<25 cm), shallow (25-50 cm), moderately shallow (50-75 cm), moderately deep (75-100 cm), deep (100-150 cm) and very deep (>150 cm). They were used to classify the soils into different depth classes and a soil depth map was generated (Fig. 5.2).

An area of about 103 ha (22%) is shallow (25-50 cm) and are distributed in the southern, central and northern part of the microwatershed. Very shallow (<25 cm) soils occupy a negligible area. Moderately shallow soils (50-75 cm) occupy an area of about 26 ha (6%) and occur in the northwestern part of the microwatershed. Maximum area of about 194 ha (11%) is moderately deep (75-100 cm) and are distributed in the northeastern, eastern and central part of the microwatershed. Deep (100-150 cm) soils occupy an area of about 35 ha (7%) and occur in the northern and southeastern part of the microwatershed. Very deep (>150 cm) soils occupy an area of about 104 ha (22%) and are distributed in the western and southwestern part of the microwatershed.

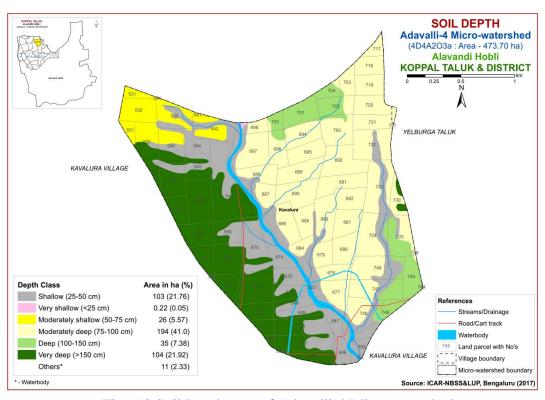

Fig. 5.2 Soil Depth map of Adavalli-4 Microwatershed

The most problem lands with an area of about 103 ha (22%) having shallow (<25 cm) rooting depth. They are not suitable for growing agricultural crops but well suited for pasture, forestry or other recreational purposes. Occasionally, short duration crops may be grown if rainfall is normal. The most productive lands cover about 139 ha (29%) having deep to very deep (100->150 cm) where all climatically adopted long duration crops be grown.

5.3 Surface Soil Texture

Texture is an expression to indicate the coarseness or fineness of the soil as determined by the relative proportion of primary particles of sand, silt and clay. It has a direct bearing on the structure, porosity, adhesion and consistence. The surface layer of a soil to a depth of about 25 cm is the layer that is most used by crops and plants. The surface soil textural class provides a guide to understanding soil-water retention and availability, nutrient holding capacity, infiltration, workability, drainage, physical and chemical behaviour, microbial activity and crop suitability.

The soils in the entire microwatershed are clayey at the surface (Fig. 5.3). The entire area has most productive lands that have high potential for soil-water retention and availability, and nutrient retention and availability, but have problems of drainage, infiltration, workability and other physical problems in clayey soils.

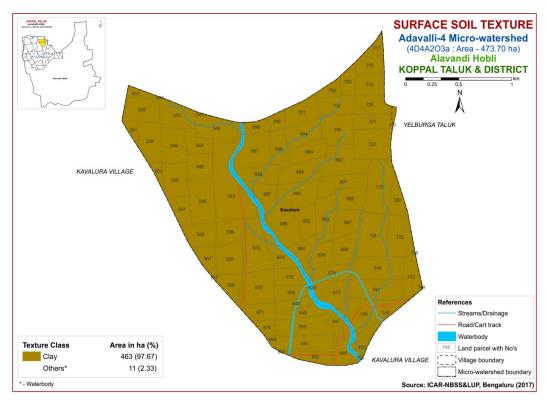

Fig. 5.3 Surface Soil Texture map of Adavalli-4 Microwatershed

5.4 Soil Gravelliness

Gravel is the term used for describing coarse fragments between 2 mm and 7.5 cm diameter and stones for those between 7.5 cm and 25 cm. The presence of gravel and

stones in soil reduces the volume of soil responsible for moisture and nutrient storage, drainage, infiltration and runoff, and hinders plant growth by impeding root growth and seedling emergence, intercultural operations and farm mechanization.

The soils that are non-gravelly (<15% gravel) cover an area of about 333 ha (70%) and are distributed in all parts of the microwatershed. An area of 123 ha (26%) is covered by gravelly (15-35% gravel) soils and are distributed in the southern, central and northern part of the microwatershed. A small area of about 7 ha (2%) has soils that are extremely gravelly (60-80% gravel) and are distributed in the central part of the microwatershed (Fig. 5.4).

The most productive lands with respect to non gravelliness are found to 70%. They are non-gravelly with less than 15 per cent gravel and have potential for growing both annual and perennial crops. The problem soils (28%) that are gravelly (15-35%) and extremely gravelly (60-80%) where only short duration crops can be grown.

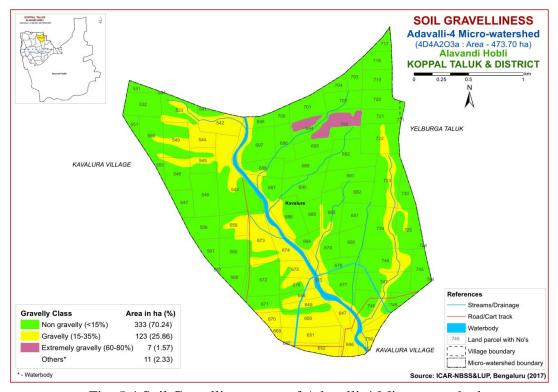

Fig. 5.4 Soil Gravelliness map of Adavalli-4 Microwatershed

5.5 Available Water Capacity

The soil available water capacity (AWC) is estimated based on the ability of the soil column to retain water between the tensions of 0.33 and 15 bar in a depth of 100 cm or the entire solum if the soil is shallower. The AWC of the soils (soil series) as estimated by considering the soil texture, mineralogy, soil depth and gravel content (Sehgal *et al.*, 1990) and accordingly the soil map units were grouped into five AWC classes *viz*, very low (<50 mm/m), low (50-100 mm/m), medium (100-150 mm/m), high (150-200 mm/m) and very high (>200 mm/m) and using these values, an AWC map was generated (Fig. 5.5).

Negligible area is very low (<50 mm/m) in available water capacity. An area of about 129 ha (27%) has soils that are low (51-100 mm/m) in available water capacity and are distributed in the northern, central and southern part of the microwatershed. An area of about 194 ha (41%) is medium (101-150 mm/m) in available water capacity and are distributed in the northwestern part of the microwatershed and about 139 ha (29%) area is very high in available water capacity and are distributed in the northeastern and southeastern part of the microwatershed.

An area of about 129 ha (27%) in the microwatershed has soils that are problematic with regard to available water capacity. Here, only short duration crops can be grown and the probability of crop failure is very high. These areas are best put to other alternative uses. An area of about 139 ha (29%) has soils that have high potential (>200 mm/m) with regard to available water capacity where all climatically adapted long duration crops can be grown successfully.

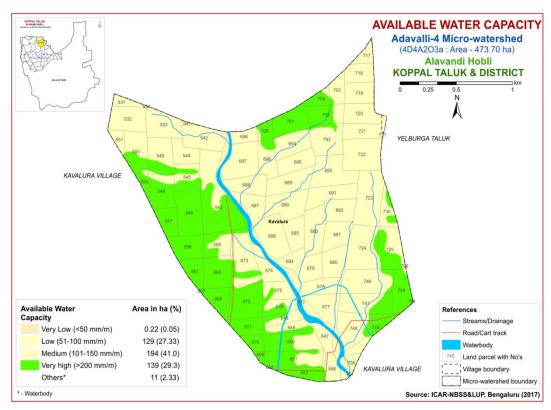

Fig. 5.5 Soil Available Water Capacity map of Adavalli-4 Microwatershed

5.6 Soil Slope

Soil slope refers to the inclination of the surface of the land. It is defined by gradient, shape and length, and is an integral feature of any soil as a natural body. Slope is considered important in soil genesis, land use and land development. The length and gradient of slope influences the rate of runoff, infiltration, erosion and deposition. The soil map units were grouped into four slope classes and a slope map was generated showing the area extent and their geographic distribution of different slope classes in the microwatershed (Fig. 5.6).

Entire area falls under very gently sloping (1-3% slope) lands. In all these areas, all climatically adapted annual and perennial crops can be grown without much soil and water conservation and other land development measures.

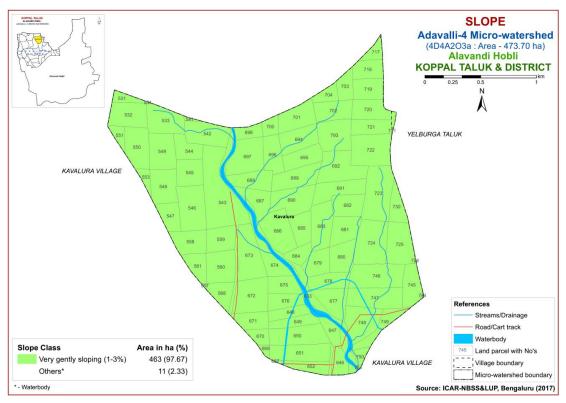

Fig. 5.6 Soil Slope map of Adavalli-4 Microwatershed

5.7 Soil Erosion

Soil erosion refers to the wearing away of the earth's surface by the forces of water, wind and ice involving detachment and transport of soil by raindrop impact. It is used for accelerated soil erosion resulting from disturbance of the natural landscape by burning, excessive grazing and indiscriminate felling of forest trees and tillage, all usually by man. The erosion classes showing an estimate of the current erosion status as judged from field observations in the form of rills, gullies or a carpet of gravel on the surface are recorded. Four erosion classes, viz, slight erosion (e1), moderate erosion (e2), severe erosion (e3) and very severe erosion (e4) are recognized. The soil map units were grouped into different erosion classes and a soil erosion map generated. The area extent and their spatial distribution in the microwatershed is given in Figure 5.7.

Entire area has moderately eroded (e2 class) soils. These are problematic and need appropriate soil and water conservation and other land development measures.

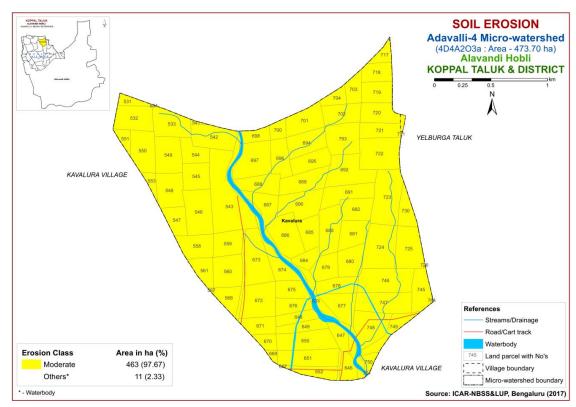

Fig. 5.7 Soil Erosion map of Adavalli-4 Microwatershed

FERTILITY STATUS

Soil fertility plays an important role in increasing crop yield. The adoption of high yielding varieties that require high amounts of nutrients has resulted in deficiency symptoms in crops and plants due to imbalanced fertilization and poor inherent fertility status, as these areas are characterised by low rainfall and high temperatures. Hence, it is necessary to know the fertility (macro and micro nutrients) status of the soils of the watersheds for assessing the kind and amount of fertilizers required for each of the crop intended to be grown. For this purpose, the surface soil samples collected from the grid points (one soil sample at every 250 m grid interval) all over the microwatershed through land resource inventory in the year 2017 were analysed for pH, EC, organic carbon, available phosphorus and potassium and for micronutrients like zinc, boron, copper, iron and manganese, and secondary nutrient sulphur.

Soil fertility data generated has been assessed and individual maps for all the nutrients for the microwatershed have been generated by using the Kriging method. The village/survey number wise fertility data for the microwatershed is given in Appendix-II.

6.1 Soil Reaction (pH)

The soil analysis of the Adavalli-4 microwatershed for soil reaction (pH) showed that an area of about 134 ha (28%) is strongly alkaline (pH 8.4-9.0) and is distributed in the southern and northwestern part of the microwatershed. Major area of about 328 ha (69%) is very strongly alkaline (pH >9.0) and is distributed in the major part of the microwatershed (Fig.6.1). Thus, all the soils in the microwatershed are alkaline in reaction.

6.2 Electrical Conductivity (EC)

The Electrical Conductivity of the soils of the entire microwatershed area is <2 dSm⁻¹ (Fig 6.2) and as such the soils are nonsaline.

6.3 Organic Carbon

The soil organic carbon content (an index of available Nitrogen) of the microwatershed is medium (0.5-0.75%) covering maximum area of about 185 ha (39%) and is distributed in the southern, western, northwestern and northeastern part of the microwatershed. An area of 159 ha (36%) is low (<0.5%) in organic carbon content and is distributed in the northern, northwestern and eastern part of the microwatershed. An area of about 119 ha (25%) is high (>0.75%) in organic carbon content and occur in the central part of the microwatershed (Fig.6.3).

6.4 Available Phosphorus

Major area of about 452 ha (96%) is low (<23 kg/ha) in available phosphorus and occur in all parts of the microwatershed. A very small area of about 10 ha (2%) is

medium (23-57 kg/ha). There is an urgent need to increase the dose of phosphorous for all the crops by 25 per cent over the recommended dose to realize better crop performance (Fig 6.4).

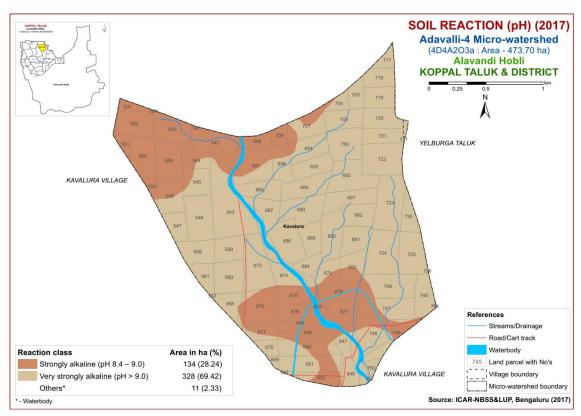

Fig. 6.1 Soil Reaction (pH) map of Adavalli-4 Microwatershed

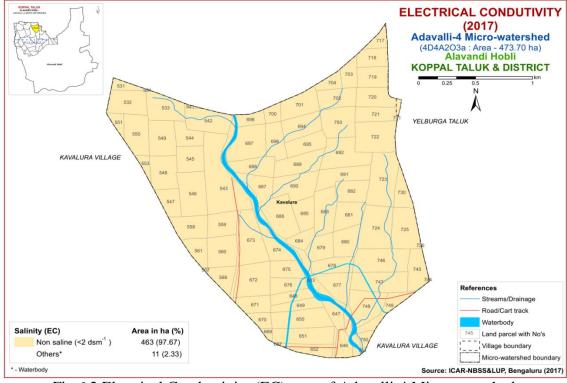

Fig. 6.2 Electrical Conductivity (EC) map of Adavalli-4 Microwatershed

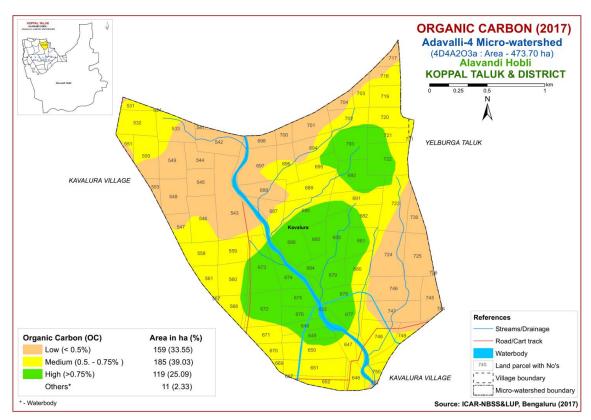

Fig. 6.3 Soil Organic Carbon map of Adavalli-4 Microwatershed

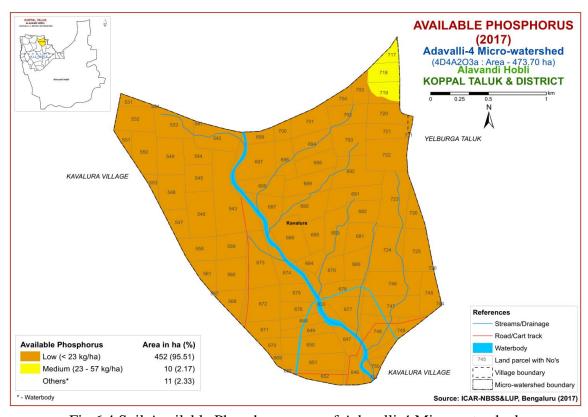

Fig. 6.4 Soil Available Phosphorus map of Adavalli-4 Microwatershed

6.5 Available Potassium

Entire area in the microwatershed is high (>337 kg/ha) in available potassium (Fig.6.5).

6.6 Available Sulphur

Major area of 287 ha (61%) is low (<10 ppm) in available sulphur and distributed in all parts of the microwatershed. Medium (10-20 ppm) in available sulphur is found in negligible area in the microwatershed. An area of about 176 ha (37%) is high (>20 ppm) in available sulphur and are distributed in the southwestern, northern, northeastern and southeastern part of the microwatershed (Fig.6.6). The areas that are low and medium in available sulphur need to be applied with magnesium sulphate or gypsum or factomphos (p) fertilizer (13% sulphur) for 2-3 years for the deficiency to be corrected.

6.7 Available Boron

Available boron content is low (<0.5 ppm) in maximum area of 263 ha (56%) in the microwatershed and is distributed in the major part of the microwatershed. A very small area of about 9 ha (2%) is medium (0.5-1.0 ppm) in available boron and is distributed in the northern part of the microwatershed. An area of about 190 ha (40%) and is distributed in the western, northeastern and northern part of the microwatershed (Fig.6.7).

6.8 Available Iron

Available iron content is sufficient (>4.5 ppm) in the entire microwatershed area (Fig 6.8).

6.9 Available Manganese

Available manganese content is sufficient (>1.0 ppm) in the entire microwatershed area (Fig 6.9).

6.10 Available Copper

Available copper content is sufficient (>0.2 ppm) in the entire microwatershed area (Fig 6.10).

6.11 Available Zinc

Available zinc content is deficient (<0.6 ppm) in the entire microwatershed area (Fig 6.11).

LAND SUITABILITY FOR MAJOR CROPS

The soil and land resource units (soil phases) of Adavalli-4 Microwatershed were assessed for their suitability for growing food, fodder, fibre and other horticulture crops by following the procedure as outlined in FAO, 1976 and 1983. Crop requirements were developed for each of the crop from the available research data and also by referring to Naidu et. al. (2006) and Natarajan et. al (2015). The crop requirements were matched with the soil and land characteristics (Table 7.1) to arrive at the crop suitability. In FAO land suitability classification, two orders are recognized. Order S- Suitable and Order N-Not suitable. The orders have classes, subclasses and units. Order-S has three classes, Class S1- Highly Suitable, Class S2- Moderately Suitable and Class S3- Marginally Suitable. Order N has two Classes, N1- Currently not Suitable and N2- Permanently not Suitable. There are no subclasses within the Class S1 as they will have very minor or no limitations for crop growth. Classes S2, S3, N1 and N2 are divided into subclasses based on the kinds of limitations encountered. The limitations that affect crop production are 'c' for erratic rainfall and its distribution and length of growing period (LGP), 'e' for erosion hazard, 'r' for rooting condition, 't' for lighter or heavy texture, 'g' for gravelliness or stoniness, 'n' for nutrient availability, 'l' for topography, 'm' for moisture availability, 'z' for calcareousness and 'w' for drainage. These limitations are indicated as lower case letters to the class symbol. For example, moderately suitable lands with the limitations of soil depth and erosion are designated as S2re. For the microwatershed, the soil mapping units were evaluated and classified up to subclass level.

Using the above criteria, the soil map units of the microwatershed were evaluated and land suitability maps for 24 major annual and perennial crops were generated. The detailed information on the kind of suitability of each of the soil phase for the crops assessed are given village/ survey number wise for the microwatershed in Appendix-III.

7.1 Land Suitability for Sorghum (Sorghum bicolor)

Sorghum is one of the major crop grown in Karnataka in an area of 10.47 lakh ha in Bijapur, Gulbarga, Raichur, Bidar, Belgaum, Dharwad, Bellary, Chitradurga, Mysore and Chamarajnagar districts. The crop requirements for growing sorghum (Table 7.2) were matched with the soil-site characteristics (Table 7.1) of the soils of the microwatershed and land suitability map for growing sorghum was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure. 7.1.

Highly suitable (Class S1) land ccupying a major area of about 260 ha (55%) for growing sorghum occur in the major part of the microwatershed. An area of about 91 ha (19%) is moderately suitable (Class S2) for growing sorghum and are distributed in the northern, northwestern and central part of the microwatershed.

^{*}Symbols and abbreviations are according to Field Guide for LRI under Sujala-III Project, Karnataka

They have minor limitations of rooting depth, nutrient availability and calcareousness. Marginally suitable (Class S3) lands cover an area of about 103 ha (22%) and occur in the southern, central and northern part of the microwatershed and have moderate limitations of rooting depth and calcareousness. A very small area of about 7 ha (2%) is not suitable (Class N1) for growing sorghum and occur in the northeastern part of the microwatershed with severe limitations of gravelliness and rooting depth.

7.2 Land Suitability for Maize (Zea mays)

Maize is the most important food crop grown in an area of 13.37 lakh ha in almost all the districts of the State. The crop requirements for growing maize (Table 7.3) were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing maize was generated. The area extent and their geographical distribution of different suitability subclasses in the microwatershed is given in Figure 7.2.

Table 7.3 Crop suitability criteria for Maize

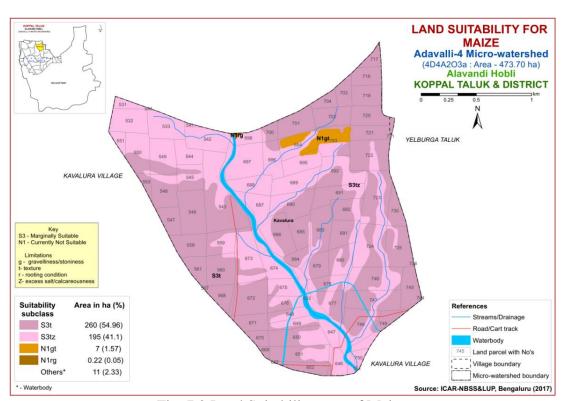

Fig. 7.2 Land Suitability map of Maize

There are no highly (S1) and moderately suitable (S2) lands for growing maize. Marginally suitable (Class S3) lands cover a maximum area of about 455 ha (96%) and occur in all parts of the microwatershed. They have moderate limitations of texture and

calcareousness and a small area of about 7 ha (2%) is not suitable (Class N1) for growing maize and occur in the central part of the microwatershed with severe limitations of gravelliness, rooting depth and texture.

7.3 Land Suitability for Bajra (Pennisetum glaucum)

Bajra is one of the major food crop grown in an area of 2.34 lakh ha in Karnataka in the northern districts. The crop requirements for growing bajra were matched with the soil-site characteristics (Table 7.1) of the soils of the microwatershed and land suitability map for growing bajra was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.3.

There are no highly (S1) and moderately suitable (S2) lands for growing Bajra. Marginally suitable (Class S3) lands cover a maximum area of about 455 ha (96%) and occur in all parts of the microwatershed. They have moderate limitations of texture, rooting depth and calcareousness. A very small area of about 7 ha (2%) is not suitable (Class N1) for growing bajra and occur in the central part of the microwatershed with severe limitations of gravelliness, rooting depth and texture.

7.4 Land Suitability for Groundnut (Arachis hypogaea)

Groundnut is one of the major oilseed crop grown in an area of 6.54 lakh ha in Karnataka in most of the districts either as rainfed or irrigated crop. The crop requirements for growing groundnut (Table 7.4) were matched with the soil-site characteristics (Table 7.1) of the soils of the microwatershed and a land suitability map for growing groundnut was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.4.

An area of about 26 ha (6%) is moderately suitable (Class S2) for growing groundnut and are distributed in the northwestern part of the microwatershed. They have minor limitations of calcareousness and texture. Marginally suitable (Class S3) lands occupy major area of about 435 ha (92%) and are distributed in the major part of the microwatershed with moderate limitations of gravelliness, texture and calcareousness and very negligible area is not suitable (Class N1) for growing groundnut with severe limitations of gravelliness and rooting depth.

7.5 Land Suitability for Sunflower (*Helianthus annus*)

Sunflower is one of the most important oilseed crop grown in an area of 3.56 lakh ha in the State in all the districts. The crop requirements for growing sunflower (Table 7.5) were matched with the soil-site characteristics (Table 7.1) and a land suitability map

for growing sunflower was generated. The area extent and their geographical distribution of different suitability subclasses in the microwatershed is given in Figure 7.5.

Table 7.5 Crop suitability criteria for Sunflower

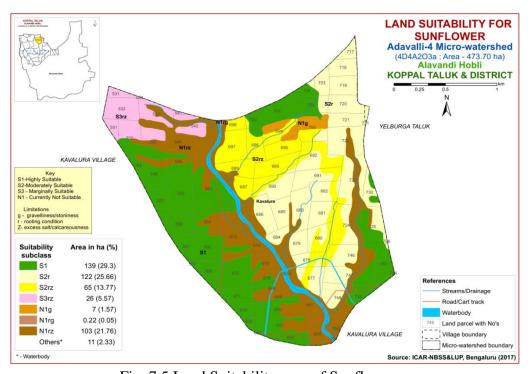

Fig. 7.5 Land Suitability map of Sunflower

An area of about 139 ha (29%) is highly suitable (Class S1) for growing sunflower and are distributed in the southwestern, western, southeastern and northern part of the microwatershed. Major area of about 187 ha (39%) is moderately suitable (Class S2) for sunflower and are distributed in the northeastern, eastern, northern and central part of the microwatershed. They have minor limitations of rooting depth and calcareousness. Marginally suitable (Class S3) lands occupy an area of about 26 ha (6%) and are distributed in the southern, central and northern part of the microwatershed with moderate limitations of gravelliness, rooting depth and calcareousness. An area of about 110 ha (23%) is not suitable (Class N1) for growing sunflower and occur in the northern and

northwestern part of the microwatershed with severe limitations of gravelliness, calcareousness and rooting depth.

7.6 Land Suitability for Chilli (Capsicum annuum L)

Chilli is one of the major fruit and spice crop grown in an area of 0.42 lakh ha in Karnataka State. The crop requirements for growing chilli (Table 7.6) were matched with the soil-site characteristics (Table 7.1) of the soils of the microwatershed and a land suitability map for growing chilli was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.6.

Moderately suitable (Class S2) lands occupy an area of about 326 ha (69%) and occur in all parts of the microwatershed. They have minor limitation of rooting depth, texture and calcareousness. Marginally suitable lands cover an area of about 33 ha (7%) and occur in the northwestern and central part of the microwatershed. They have moderate limitations of rooting depth, gravelliness and calcareousness. An area of about 103 ha (22%) is not suitable (Class N1) and occur in the southern, central and northern part of the microwatershed and they have severe limitations of rooting depth, calcareousness and gravelliness.

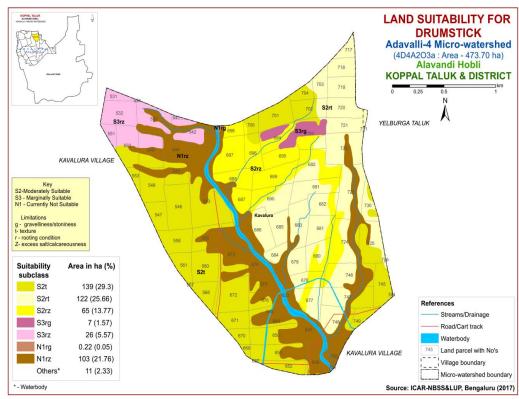

Fig. 7.8 Land Suitability map of Drumstick

7.9 Land Suitability for Mulbery (Morus nigra)

Mulbery is the most important leaf crop grown for rearing silkworms in about 1.66 lakh ha in all the districts of the state. The crop requirements for growing mulbery (Table 7.9) were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing mulbery was generated. The area extent and their geographical distribution of different suitability subclasses in the microwatershed is given in Figure 7.9.

Note: Suitability evaluation only for Mulberry leaf not for Silk worm rearing

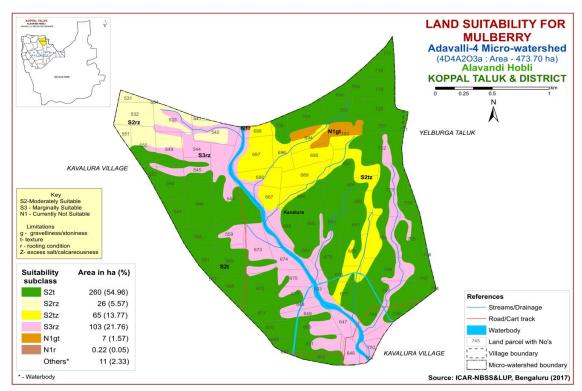

Fig. 7.9 Land Suitability map of Mulberry

Moderately suitable (Class S2) lands occupy maximum area of about 351 ha (74%) and occur in the major part of the microwatershed. They have minor limitations of rooting depth, texture and calcareousness. Marginally suitable lands cover an area of about 103 ha (22%) and occur in the southern, central and northern part of the microwatershed. They have moderate limitations of rooting depth and calcareousness. An area of about 7 ha (2%) is not suitable (Class N1) and occur in the central part of the microwatershed and they have severe limitations of rooting depth, texture and gravelliness.

7.10 Land suitability for Mango (Mangifera indica)

Mango is one of the most important fruit crop grown in about 1.73 lakh ha in almost all the districts of the State. The crop requirements (Table 7.10) for growing mango were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing mango was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.10.

There are no highly (S1) and moderately suitable (S2) lands for growing mango. Marginally suitable (Class S3) lands cover a maximum area of about 326 ha (69%) and occur in all parts of the microwatershed. They have moderate limitations of rooting depth, texture and calcareousness and about 136 ha (29%) is not suitable (Class N1) for growing mango and occur in the southern, central and northern part of the microwatershed with severe limitations of gravelliness, texture, rooting depth and calcareousness.

7.11 Land suitability for Sapota (Manilkara zapota)

Sapota is one of the most important fruit crop grown in an area of about 29373 ha in almost all the districts of the state. The crop requirements (Table 7.11) for growing sapota were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing sapota was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.11.

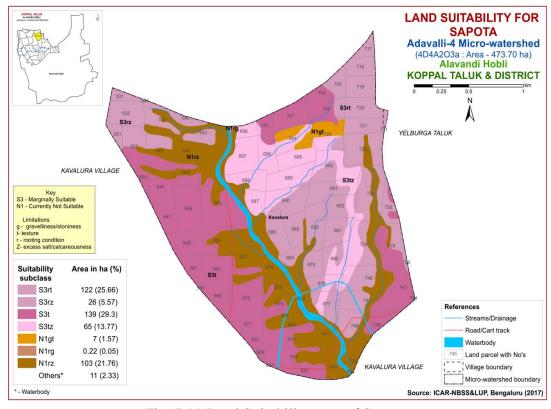

Fig. 7.11 Land Suitability map of Sapota

There are no highly (S1) and moderately suitable (S2) lands for growing sapota. Marginally suitable (Class S3) lands cover a maximum area of about 352 ha (74%) and occur in all parts of the microwatershed. They have moderate limitations of rooting depth, texture and calcareousness. An area of about 110 ha (23%) is not suitable (Class N1) for growing sapota and occur in the southern, central and northern part of the microwatershed with severe limitations of rooting depth, gravelliness, texture and calcareousness.

7.12 Land Suitability for Pomegranate (*Punica granatum*)

Pomegranate is one of the commercially grown fruit crop in about 18488 ha in Karnataka mainly in Bijapur, Bagalkot, Koppal, Gadag and Chitradurga districts. The crop requirements for growing pomegranate (Table 7.12) were matched with the soil-site characteristics (Table 7.1) of the soils of the microwatershed and a land suitability map for growing pomegranate was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.12.

Moderately suitable (Class S2) lands for growing pomegranate occupy an area of about 326 ha (69%) and occur in all parts of the microwatershed. They have minor limitation of rooting depth and texture. Marginally suitable lands occupy an area of about 33 ha (7%) and occur in the northwestern and central part of the microwatershed. They have moderate limitations of rooting depth, gravelliness, texture and calcareousness. An area of about 103 ha (22%) is not suitable (Class N1) and occur in the southern, central and northern part of the microwatershed and they have severe limitations of rooting depth, calcareousness and gravelliness.

7.13 Land suitability for Guava (*Psidium guajava*)

Guava is one of the most important fruit crop grown in an area of about 6558 ha in almost all the districts of the state. The crop requirements (Table 7.13) for growing guava were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing guava was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.13.

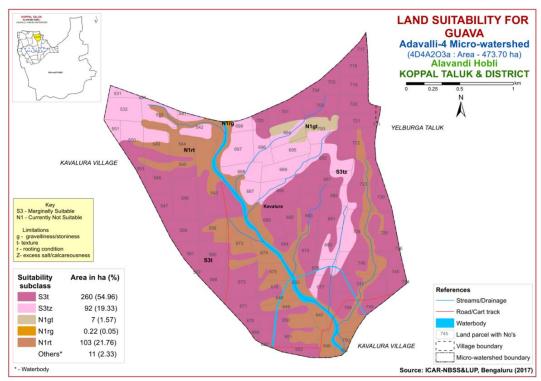

Fig. 7.13 Land Suitability map of Guava

There is no highly (S1) and moderately suitable (S2) lands for growing guava. Marginally suitable (Class S3) lands cover a maximum area of about 352 ha (74%) and occur in all parts of the microwatershed. They have moderate limitations of texture and calcareousness. An area of about 110 ha (23%) is not suitable (Class N1) for growing guava and occur in the southern, central and northern part of the microwatershed with severe limitations of rooting depth, gravelliness and texture.

7.14 Land Suitability for Jackfruit (Artocarpus heterophyllus)

Jackfruit is one of the most important fruit crop grown in 5368 ha in all the districts of the state. The crop requirements for growing jackfruit were matched with the soil-site characteristics and a land suitability map for growing jackfruit was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in figure 7.14.

There are no highly (S1) and moderately suitable (S2) lands for growing jackfruit. Marginally suitable (Class S3) lands cover a maximum area of about 352 ha (74%) and occur in all parts of the microwatershed. They have moderate limitations of gravelliness, texture and calcareousness. An area of about 110 ha (23%) is not suitable (Class N1) for growing jackfruit and occur in the southern, central and northern part of the microwatershed with severe limitations of rooting depth, gravelliness and texture.

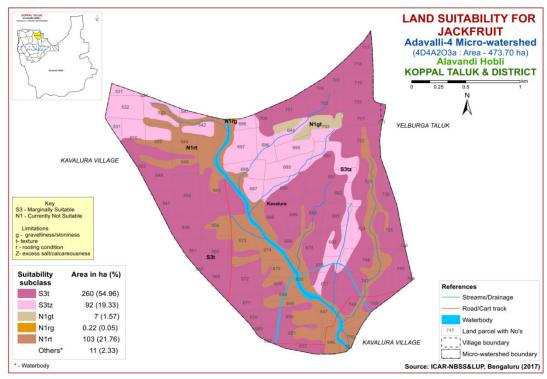

Fig. 7.14 Land Suitability map of Jackfruit

7.15 Land Suitability for Jamun (Syzygium cumini)

Jamun is an important fruit crop grown in almost all the districts of the state. The crop requirements for growing jamun were matched with the soil-site characteristics and a land suitability map for growing jamun was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.15.

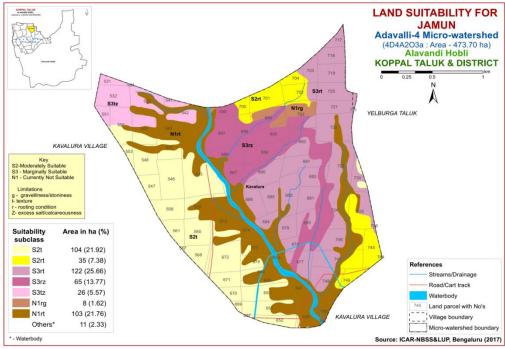

Fig. 7.15 Land Suitability map of Jamun

There are no highly suitable (Class S1) lands for growing jamun. An area of about 139 ha (29%) is moderately suitable (Class S2) and occur in the western, southwestern, northern and southeastern part of the microwatershed. They have minor limitations of rooting depth and texture. The marginally suitable (Class S3) lands cover a maximum area of about 213 ha (45%) and are distributed in the northwestern, northeastern, central and eastern part of the microwatershed with moderate limitations of rooting depth, calcareousness and texture. An area of about 111 ha (23%) is not suitable for growing jamun and are distributed in the southern, central and northern part of the microwatershed and have severe limitations of rooting depth, gravelliness and texture.

7.16 Land Suitability for Musambi (Citrus limetta)

Musambi is one of the most important fruit crop grown in an area of 5446 ha in almost all the districts of the state. The crop requirements for growing musambi were matched with the soil-site characteristics (Table 7.14) and a land suitability map for growing musambi was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.16.

An area of about 139 ha (29%) is highly suitable (Class S1) for growing musambi and are distributed in the western, southwestern, northern and southeastern part of the microwatershed. Major area of about 187 ha (39%) is moderately suitable (Class 2) and occurs in the northern, northeastern, central and eastern part of the microwatershed. They have minor limitations of rooting depth and calcareousness. An area of about 26 ha (6%) is marginally suitable (Class S3) for growing musambi and are distributed in the northwestern part of the microwatershed with moderate limitations of calcareousness and rooting depth. An area of about 111 ha (23%) is not suitable (Class N) for growing musambi and are distributed in the southern, central and northern part of the microwatershed with severe limitations of rooting depth, gravelliness and calcareousness.

Table 7.14 Crop suitability criteria for Musambi

7.17 Land Suitability for Lime (Citrus sp)

Lime is one of the most important fruit crop grown in an area of 11752 ha in almost all the districts of the State. The crop requirements for growing lime (Table 7.15) were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing lime was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.17.

Table 7.15 Crop suitability criteria for Lime

Crop	requirement		Rating

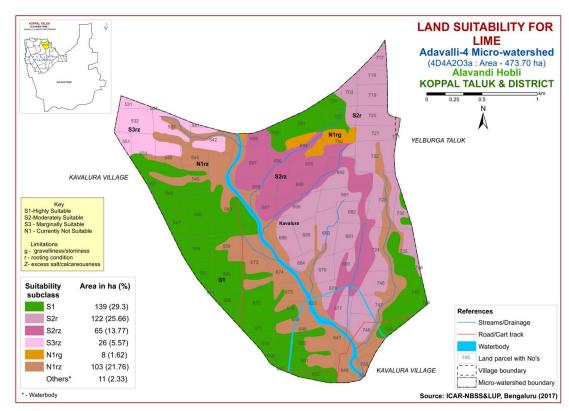

Fig. 7.17 Land Suitability map of Lime

An area of about 139 ha (29%) is highly suitable (Class S1) for growing lime and are distributed in the western, southwestern, northern and southeastern part of the microwatershed. Major area of about 187 ha (39%) is moderately suitable (Class 2) and occurs in the northern, northeastern, central and eastern part of the microwatershed. They have minor limitations of rooting depth and calcareousness. An area of about 26 ha (6%) is marginally suitable (Class S3) for growing lime and are distributed in the northwestern part of the microwatershed with moderate limitations of calcareousness and rooting depth. An area of about 111 ha (23%) is not suitable (Class N) for growing lime and are distributed in the southern, central and northern part of the microwatershed with severe limitations of rooting depth, gravelliness and calcareousness.

7.18 Land Suitability for Cashew (Anacardium occidentale)

Cashew is one of the most important nut crop grown in an area of 7052 ha in almost all the districts of the State. The crop requirements for growing cashew were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing cashew was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.18.

Entire area is not suitable (Class N1) for growing cashew in the microwatershed with limitations of texture, gravelliness, rooting depth and calcareousness.

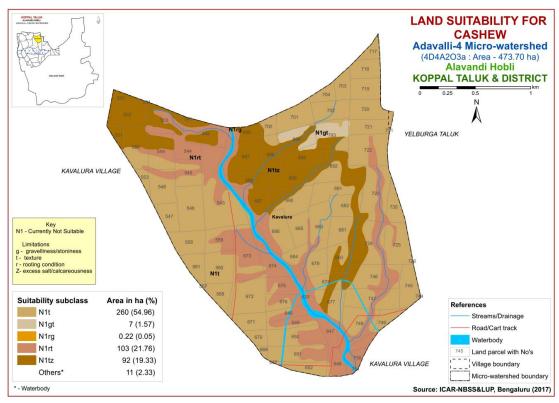

Fig. 7.18 Land Suitability map of Cashew

7.19 Land Suitability for Custard Apple (Annona reticulata)

Custard apple is one of the most important fruit crop grown in 1426 ha in almost all the districts of the State. The crop requirements for growing custard apple were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing custard apple was generated .The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.19.

Major area of about 260 ha (55%) is highly suitable (Class S1) for growing custard apple. They are distributed in all parts of the microwatershed. An area of about 91 ha (19%) is moderately suitable (Class S2) and occur in the northwestern, northern and central part of the microwatershed. They have minor limitations of rooting depth and calcareousness. Marginally suitable (Class S3) lands occupy an area of about 110 ha (23%) for growing custard apple and are distributed in the southern, central and northern part of the microwatershed with moderate limitations of calcareousness and gravelliness and very negligible area is not suitable (Class N1) for growing custard apple with severe limitations of rooting depth and gravelliness.

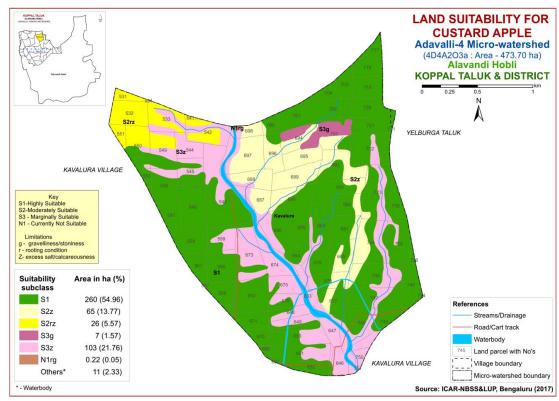

Fig. 7.19 Land Suitability map of Custard Apple

7.20 Land Suitability for Amla (Phyllanthus emblica)

Amla is one of the most important fruit and medicinal crop grown in an area of 151 ha and distributed in almost all the districts of the state. The crop requirements for growing amla were matched with the soil-site characteristics and a land suitability map for growing amla was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed are given in Figure 7.20.

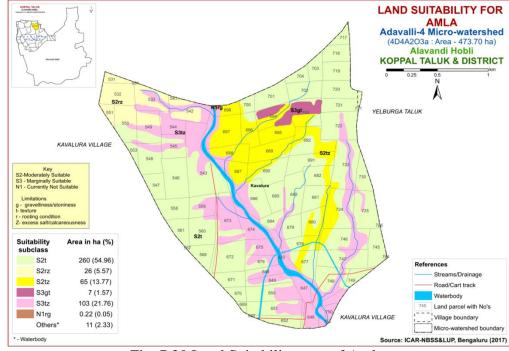

Fig. 7.20 Land Suitability map of Amla

Maximum area of about 351 ha (74%) has soils that are moderately suitable (Class S2) and are distributed in the major part of the microwatershed. They have minor limitations of rooting depth, calcareousness and texture. The marginally suitable (Class S3) lands cover an area of about 110 ha (23%) and occur in the southern, central and northern part of the microwatershed with moderate limitation of rooting depth, gravelliness and texture and very minute negligible area is not suitable (Class N1) for growing amla with severe limitations of rooting depth and gravelliness.

7.21 Land Suitability for Tamarind (*Tamarindus indica*)

Tamarind is one of the most important spice crop grown in 14897 ha in all the districts of the state. The crop requirements for growing tamarind were matched with the soil-site characteristics and a land suitability map for growing tamarind was generated. The area extent and their geographical distribution of different suitability subclasses in the microwatershed is given in Figure 7.21.

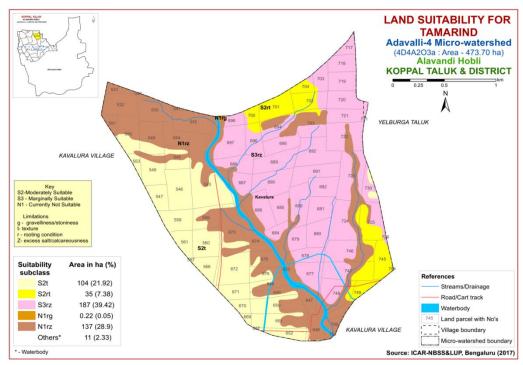

Fig. 7.21 Land Suitability map of Tamarind

There are no highly suitable lands (Class S1) for growing tamarind. An area of about 139 ha (29%) is moderately suitable (Class S2) and occurs in the northern, southwestern, western and southeastern part of the microwatershed. They have minor limitations of texture and rooting depth. Maximum area of about 187 ha (39%) is marginally suitable (Class S3) and occur in the northern, central, northeastern and eastern part of the microwatershed. They have moderate limitations of rooting depth and calcareousness. An area of about 137 ha (29%) is not suitable (Class N1) for growing tamarind and are distributed in the southern, central and northwestern part of the microwatershed. They have severe limitations of rooting depth, gravelliness and calcareousness.

7.22 Land Suitability for Marigold (*Tagetes erecta*)

Marigold is one of the most important flower crop grown in an area of 9108 ha in almost all the districts of the state. The crop requirements for growing marigold were matched with the soil-site characteristics and a land suitability map for growing marigold was generated. The area extent and their geographical distribution of different suitability subclasses in the microwatershed is given in Figure 7.22.

Maximum area of about 351 ha (74%) has soils that are moderately suitable (Class S2) and are distributed in the major part of the microwatershed. They have minor limitations of rooting depth, calcareousness and texture. The marginally suitable (Class S3) lands cover an area of about 103 ha (22%) and occur in the southern, central and northern part of the microwatershed with moderate limitation of rooting depth, gravelliness and texture and a very small area of about 7 ha (2) is not suitable (Class N1) for growing marigold with severe limitations of texture and gravelliness.

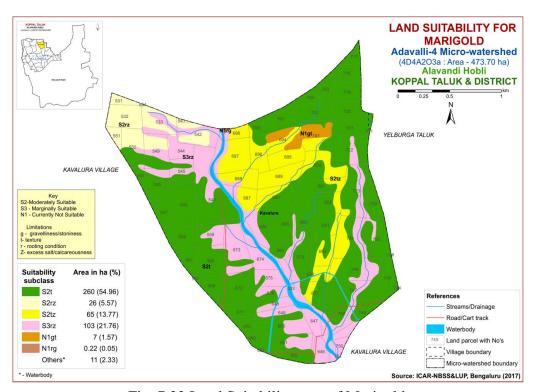

Fig. 7.22 Land Suitability map of Marigold

7.23 Land Suitability for Chrysanthemum (*Chrysanthemum indicum*)

Chrysanthemum is one of the most important flower crop grown in an area of 4978 ha in almost all the districts of the State. The crop requirements for growing chrysanthemum were matched with the soil-site characteristics and a land suitability map for growing chrysanthemum was generated. The area extent and their geographic distribution of different suitability subclasses in the microwatershed is given in Figure 7.23.

Maximum area of about 351 ha (74%) is moderately suitable (Class S2) for growing chrysanthemum and are distributed in the major part of the microwatershed.

They have minor limitations of rooting depth, calcareousness and texture. The marginally suitable (Class S3) lands cover an area of about 103 ha (22%) and occur in the southern, central and northern part of the microwatershed with moderate limitation of rooting depth, gravelliness and texture and a very small area of about 7 ha (2) is not suitable (Class N1) for growing chrysanthemum with severe limitations of texture and gravelliness.

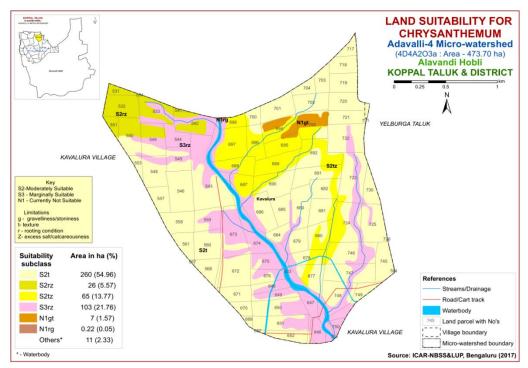

Fig. 7.23 Land Suitability map of Chrysanthemum

7. 24 Land Suitability for Jasmine (Jasminum sp.)

Jasmine is the most important flower crop grown in an area of 803 ha in almost all the districts of the State. The crop requirements (Table 7.17) for growing jasmine were matched with the soil-site characteristics (Table 7.1) and a land suitability map for growing jasmine was generated. The area extent and their geographical distribution of different suitability subclasses in the microwatershed are given in Figure 7.24.

An area of about 26 ha (6%) is moderately suitable (Class S2) for growing jasmine and occur in the northwestern part of the microwatershed. They have minor limitations of rooting depth and calcareousness. Maximum area of about 428 ha (90%) is marginally suitable (Class S3) for growing jasmine and occur in the major part of the microwatershed. They have moderate limitations of rooting depth texture and calcareousness and about very minute area are not suitable (Class N1) for growing jasmine with severe limitations of rooting depth, gravelliness and texture.

Table 7.16 Land suitability criteria for jasmine (irrigated)

Crop	requirement		Rating				
Soil-site characteristics		Unit	Highly suitable(S1)	Moderately suitable(S2)	Marginally suitable(S3)	Not suitable(N)

7.25 Land Use Classes (LUCs)

The 11 soil map units identified in Adavalli-4 microwatershed have been grouped into 5 Land Use Classes (LUCs) for the purpose of preparing a Proposed Crop Plan. Land Use Classes are grouped based on the similarities in respect of the type of soil, the depth of the soil, the surface soil texture, gravel content, AWC, slope, erosion etc. and a Land Use Class map (Fig.7.25) has been generated. These Land Use Classes are expected to behave similarly for a given level of management.

The map units that have been grouped into 5 Land Use Classes along with brief description of soil and site characteristics are given below.

LUCs No.	Mapping unit	Soil and site characteristics
1	KDTmB2 KDTmB2g1 BDRmB2	Very deep, black clayey soils with slopes of 1-3%, moderate erosion, gravelly (15-35%)
2	NSPmB2 NSPmB2g3 HDLmB2 DRLmB2	Moderately deep to deep calcareous black clayey soils with slopes of 1-3%, moderate erosion, extremely gravelly (60-80%)
3	RNKmB2 RNKmB2g1	Moderately shallow, calcareous black gravelly clayey soils with slopes of 1-3%, moderate erosion, gravelly (15-35%)
4	MTLmB2g1	Shallow, calcareous black gravelly clayey soils with slopes of 1-3%, moderate erosion, and gravelly (15-35%)
5	BGTmB2g1	Very shallow, calcareous black gravelly clayey soils with slopes of 1-3%, moderate erosion, gravelly (15-35%)

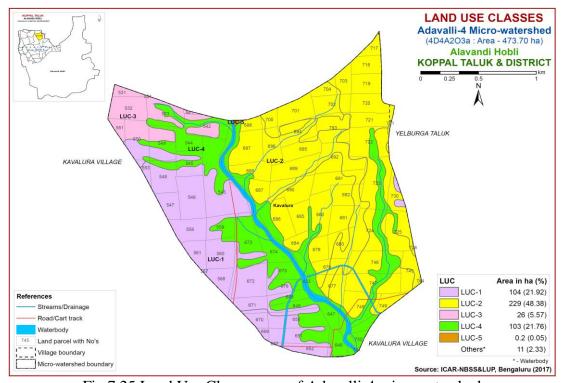

Fig 7.25 Land Use Classes map of Adavalli-4 microwatershed

7.26 Proposed Crop Plan for Adavalli-4 Microwatershed

After assessing the land suitability for the 24 crops, the proposed crop plan has been prepared for the 5 identified LUCs by considering only the highly (Class S1) and moderately (Class S2) suitable lands for each of the 24 crops. The resultant proposed crop plan is presented in Table 7.17.

Table 7.17 Proposed Crop Plan for Adavalli-4 Microwatershed

SOIL HEALTH MANAGEMENT

8.1 Soil Health

Soil is fundamental to crop production. Without soil, no food could be produced nor would livestock be fed on a large scale. Because it is finite and fragile, soil is a precious resource that requires special care from its users.

Soil health or the capacity of the soil to function is critical to human survival. Soil health has been defined as: "the capacity of the soil to function as a living system without adverse effect on the ecosystem". Healthy soils maintain a diverse community of soil organisms that help to form beneficial symbiotic associations with plant roots, recycle essential plant nutrients, improve soil structure with positive repercussions for soil, water and nutrient holding capacity and ultimately improve crop production and also contribute to mitigating climate change by maintaining or increasing its carbon content.

Functional interactions of soil biota with organic and inorganic components, air and water determine a soil's potential to store and release nutrients, and water to plants and to promote and sustain plant growth. Thus, maintaining soil health is vital to crop production and conserve soil resource base for sustaining agriculture.

The most important characteristics of a healthy soil are

- ➤ Good soil tilth
- > Sufficient soil depth
- ➤ Good water storage and good drainage
- Adequate supply, but not excess of nutrients
- ➤ Large population of beneficial organisms
- > Small proportion of plant pathogens and insect pests
- ➤ Low weed pressure
- Free of chemicals and toxins that may harm the crop
- ➤ Resistance to degradation
- Resilience when unfavorable conditions occur

Characteristics of Adavalli-4 Microwatershed

- ❖ The soil phases with sizeable area identified in the microwatershed belonged to the soil series of NSP (129 ha), MTL (103 ha), BDR (86 ha), DRL (65 ha), HDL (35 ha), RNK (27 ha), KDT (25 ha) and BGT (<1 ha).
- ❖ As per land capability classification, entire area in the microwatershed falls under arable land category (Class III and IV). The major limitations identified in the arable lands were soil and erosion.
- ❖ On the basis of soil reaction, maximum area of about 328 ha (69%) is very strongly alkaline (pH >9.0). An area of about 134 ha (28%) is under strongly alkaline (pH

8.4-9.0) in reaction. Thus, all the soils are alkaline in reaction in the microwatershed.

Soil Health Management

The following actions are required to improve the current land husbandry practices that provide a sound basis for the successful adoption of sustainable crop production system.

Alkaline soils

(Slightly alkaline to strongly alkaline soils)

- 1. Regular addition of organic manure, green manuring, green leaf manuring, crop residue incorporation and mulching needs to be taken up to improve the soil organic matter status.
- 2. Application of biofertilizers (Azospirullum, Azatobacter, Rhizobium).
- 3. Application of 25% extra N and P (125 % RDN&P).
- 4. Application of $ZnSO_4 12.5$ kg/ha (once in three years).
- 5. Application of Boron -5 kg/ha (once in three years).

Neutral soils

- 1. Regular addition of organic manure, green manuring, green leaf manuring, crop residue incorporation and mulching needs to be taken up to improve the soil organic matter status.
- 2. Application of biofertilizers, (Azospirullum, Azotobacter, Rhizobium).
- 3. Application of 100 per cent RDF.
- 4. Need based micronutrient applications.

Besides the above recommendations, the best transfer of technology options are also to be adopted.

Soil Degradation

Soil erosion is one of the major factors affecting the soil health in the microwatershed. The entire area is suffering from moderate erosion. These areas need immediate soil and water conservation and, other land development and land husbandry practices for restoring soil health.

Dissemination of Information and Communication of Benefits

Any large scale implementation of soil health management requires that supporting information is made available widely, particularly through channels familiar to farmers and extension workers. Given the very high priority attached to soil health especially by the Central Government on issuing Soil-Health Cards to all the farmers, media outlets like Regional, State and National Newspapers, Radio and Doordarshan programs in local languages but also modern information and communication technologies such as Cellular phones and the Internet, which can be much more effective in reaching the younger farmers.

Inputs for Net Planning (Saturation Plan) and Interventions needed

Net planning in IWMP is focusing on preparation of

- 1. Soil and Water Conservation Treatment Plans for each plot or farm.
- 2. Productivity enhancement measures/ interventions for existing crops/livestock/other farm enterprises.
- 3. Diversification of farming mainly with perennial horticultural crops and livestock.
- 4. Improving livelihood opportunities and income generating activities.

In this connection, how various outputs of Sujala-III are of use in addressing these objectives of Net Planning are briefly presented below.

- ❖ Soil Depth: The depth of a soil decides the amount of moisture and nutrients it can hold, what crops can be taken up or not, depending on the rooting depth and the length of growing period available for raising any crop. Deeper the soil, better for a wide variety of crops. If sufficient depth is not available for growing deep rooted crops, either choose medium or short duration crops or deeper planting pits need to be opened and additional good quality soil brought from outside has to be filled into the planting pits.
- ❖ Surface soil texture: Lighter soil texture in the top soil means, better rain water infiltration, less run-off and soil moisture conservation, less capillary rise and less evaporation losses. Lighter surface textured soils are amenable to good soil tilth and are highly suitable for crops like groundnut, root vegetables (carrot, raddish, potato etc) but not ideal for crops that need stagnant water like lowland paddy. Heavy textured soils are poor in water infiltration and percolation. They are prone for sheet erosion; such soils can be improved by sand mulching. The technology that is developed by the AICRP-Dryland Agriculture, Vijayapura, Karnataka can be adopted.
- ❖ Gravelliness: More gravel content is favorable for run-off harvesting but poor in soil moisture storage and nutrient availability. It is a significant parameter that decides the kind of crop to be raised.
- ❖ Land Capability Classification: The land capability map shows the areas suitable and not suitable for agriculture and the major constraints in each of the plot/survey number. Hence, one can decide what kind of enterprise is possible in each of these units. In general, erosion and soil are the major constraints in Adavalli-4 Microwatershed.
- ❖ Organic Carbon: The OC content is medium (0.5-0.75%) in maximum area of about 185 ha (39%), low (<0.5%) in 159 ha (34%) and high (>0.5%) in about 119 ha (25%). The areas that are low and medium in OC needs to be further improved by applying farmyard manure and rotating crops with cereals and legumes or mixed cropping.
- ❖ Promoting green manuring: Growing of green manuring crops costs Rs. 1250/ha (green manuring seeds) and about Rs. 2000/ha towards cultivation that totals to Rs. 3250/- per ha. On the other hand, application of organic manure @ 10 tons/ha costs Rs. 5000/ha. The practice needs to be continued for 2-3 years or more. Nitrogen fertilizer needs to be supplemented by 25% in addition to the recommended level in 159 ha area where OC is less than 0.5% and 185 ha area is medium (0.5-0.75%). For example, for rainfed maize,

- recommended level is 50 kg N per ha and an additional 12 kg /ha needs to be applied for all the crops grown in these plots.
- ❖ Available Phosphorus: About 452 ha (96%) area is low and 10 ha (2%) is medium in available phosphorus. Hence for all the crops, 25% additional P-needs to be applied.
- **Available Potassium:** Entire area in the microwatershed is high in available potassium.
- ❖ Available Sulphur: Available sulphur is a very critical nutrient for oilseed crops. Available sulphur is low (<10 ppm) in 287 ha (62%) area and very minute area in medium. These areas need to be applied with magnesium sulphate or gypsum or Factamphos (p) fertitilizer (13% sulphur) for 2-3 years for the deficiency to be corrected. It is high in 176 ha (37%) area of the microwatershed.
- ❖ Available Boron: Major area of about 263 ha (56%) is low (<0.5 ppm) in available boron and 190 ha (40%) is high (>1.0 ppm) in available boron content. These areas need to be applied with sodium borate @ 10kg/ha as a soil application or 0.2% borax as foliar spray to correct the deficiency and an area of 9 ha (2%) is medium (0.5-1.0 ppm)
- ❖ Available Zinc: It is deficient (<0.6 ppm) in entire area of the microwatershed. Application of zinc sulphate @ 25kg/ha is to be followed in areas that are deficient in available zinc.
- ❖ Available Iron, Manganese and Copper: It is sufficient in entire area in the microwatershed.
- ❖ Soil alkalinity: The entire area in the microwatershed has soils that are moderately to very strongly alkaline. These areas need application of gypsum and wherever calcium is in excess, iron pyrites and element sulphur can be recommended. Management practices like treating repeatedly with good quality water to drain out the excess salts and provision of subsurface drainage and growing of salt tolerant crops like Casuarina, Acasia, Neem, Ber etc, are recommended.

Land Suitability for various crops: Areas that are highly, moderately and marginally suitable for growing various crops are indicated. Along with the suitability, various constraints that are limiting the productivity are also indicated. For example, in case of cotton, gravel content, rooting depth and salinity/alkalinity are the major constraints in various plots. With suitable management interventions, the productivity can be enhanced. In order to increase water holding capacity of light textured soils, growing of green manure crops and application of organic manure is recommended.

SOIL AND WATER CONSERVATION TREATMENT PLAN

For preparing soil and water conservation treatment plan for Adavalli-4 Microwatershed, the land resource inventory database generated under Sujala-III project has been transformed as information through series of interpretative (thematic) maps using soil phase map as a base. The various thematic maps (1:7920 scale) generated were

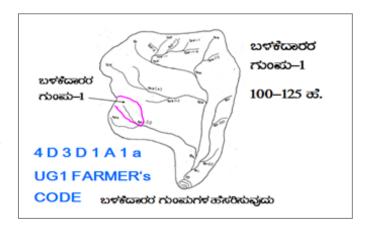

- > Soil depth
- Surface soil texture
- ➤ Available water capacity
- > Soil slope
- > Soil gravelliness
- ➤ Land capability
- > Present land use and land cover
- > Crop suitability maps
- > Rainfall map
- > Hydrology
- ➤ Water Resources
- > Socio-economic data
- ➤ Contour plan with existing features- network of waterways, pothissa boundaries, cut up/ minor terraces etc.
- Cadastral map (1:7920 scale)
- ➤ Satellite imagery (1:7920 scale)

 Apart from these, Hand Level/ Hydro Marker/ Dumpy Level/ Total Station and Kathedars' List is collected.

Steps for Survey and Preparation of Treatment Plan

The boundaries of Land User Groups' and Survey No. boundaries are traced in the field.

- ➤ Naming of user groups and farmers
- ➤ Identification of arable and non arable lands
- ➤ Identification of drainage lines and gullies
- ➤ Identification of non treatable areas
- ➤ Identification of priority areas in the arable lands
- > Treatment plan for arable lands
- ➤ Location of water harvesting and recharge structures

9.1 Treatment Plan

The treatment plan recommended for arable lands is briefly described below.

9.1.1 Arable Land Treatment

A. BUNDING

Steps for	Survey and Preparation of		USER GROUP-1
	Treatment Plan		
Cadastral maj	o (1:7920 scale) is enlarged to a		CLASSIFICATION OF GULLIES
scale of 1:250	00 scale		
Existing netw	ork of waterways, pothissa		<u>ಕೊರಕಲಿನ ವರ್ಗೀಕರಣ</u>
boundaries, g	rass belts, natural drainage		• ಮೇಲ್ಸ್ಗರ
	ourse, cut ups/ terraces are	UPPER REACH	15 Ha.
	e cadastral map to the scale		• ಮಧ್ಯಸ್ಥರ
Drainage line	s are demarcated into	MIDDLE REACH	15+10=25 ಹೆ. • ಕೆಳಸ್ತರ
Small	(up to 5 ha catchment)		25 ක්ද්ගේ බංජ පටුර
gullies		LOWED DEACH	23 mgrov nos siças
Medium	(5-15 ha catchment)	LOWER REACH	DOUNT OF CONCENTRATION
gullies			POINT OF CONCENTRATION
Ravines	(15-25 ha catchment) and		
Halla/Nala	(more than 25ha catchment)		

Measurement of Land Slope

Land slope is estimated or determined by the study and interpretation of contours or by measurement in the field using simple instruments like Hand level or Hydromarker.

Vertical and Horizontal intervals between bunds as recommended by the Watershed Development Department.

Slope percentage	Vertical interval (m)	Corresponding Horizontal Distance (m)		
2 - 3%	0.6	24		
3 - 4%	0.9	21		
4 - 5%	0.9	21		
5 - 6%	1.2	21		
6 - 7%	1.2	21		

Note: i) The above intervals are maximum.

(ii) Considering the slope Class and erosion status (A1... A= 0-1% slope, 1= slight erosion.) the intervals have to be decided.

Bund length recording: Considering the contour plan and the existing grass belts/partitions, the bunds are aligned and lengths are measured.

Section of the Bund

Bund section is decided considering the soil texture class and gravelliness class (bg₀b= loamy sand, $g_0 = <15\%$ gravel). The recommended sections for different soils are given below.

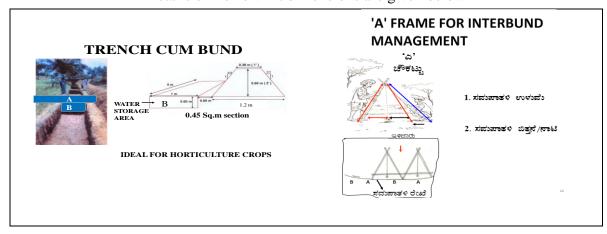

Recommended Bund Section

Top width (m)	Base width (m)	Height (m)	Side slope (Z:1;H:V)	Cross section (sq m) Soil Texture		Remarks
0.3	0.9	0.3	01:01	0.18	Sandy loam	Vegetative
0.3	1.2	0.3	1.5:1	0.225	Sandy clay	bund
0.3	1.2	0.5	0.9:1	0.375	Red gravelly soils	
0.3	1.2	0.6	0.75:1	0.45		
0.3	1.5	0.6	01:01	0.54	Red sandy loam	
0.3	2.1	0.6	1.5:1	0.72 Very shallow black clayey soils		
0.45	2	0.75	01:01	0.92		
0.45	2.4	0.75	1.3:1	1.07	Shallow black clayey soils	
0.6	3.1	0.7	1.78:1	1.29	Medium black clayey soils	
0.5	3	0.85	1.47:1	1.49		

Formation of Trench cum Bund

Dimensions of the Borrow Pits/ Trenches to be excavated (machinery are decided considering the Bund Section).

Details of Borrow Pit dimensions are given below

Size of Borrow Pits/ Trench recommended for Trench cum Bund (by machinery)

Bund section	Bund length	Earth quantity	Pit				Berm (pit to pit)	Soil depth Class
m ²	m	m^3	L(m)	W(m)	D(m)	QUANTITY (m ³)	m	
0.375	6	2.25	5.85	0.85	0.45	2.24	0.15	Shallow
0.45	6	2.7	5.4	1.2	0.43	2.79	0.6	Shallow
0.45	6	2.7	5	0.85	0.65	2.76	1	Moderately Shallow
0.54	5.6	3.02	5.5	0.85	0.7	3.27	0.1	Moderately shallow
0.54	5.5	2.97	5	1.2	0.5	3	0.5	Shallow
0.72	6.2	4.46	6	1.2	0.7	5.04	0.2	Moderately shallow
0.72	5.2	3.74	5.1	0.85	0.9	3.9	0.1	Moderately deep

B. Waterways

- a) Existing waterways are marked on the cadastral map (1:7920 scale) and their dimensions are recorded.
- **b)** Considering the contour plan of the MWS, additional waterways/ modernization of the existing ones can be thought of.
- c) The design details are given in the Manual.

C. Farm Ponds

Waterways and the catchment area will give an indication on the size of the Farm Pond. Location of the pond can be decided based on the contour plan/ field condition and farmers' need/desire.

D. Diversion channel

Existing EPT/ CPT are marked on the cadastral map. Looking to the need, these can be modernized or fresh diversion channel can be proposed and runoff from this can be stored in Gokatte/ Recharge ponds.

9.1.2 Non-Arable Land Treatment

Depending on the gravelliness and crops preferred by the farmers, the concerned authorities can decide appropriate treatment plan. The recommended treatments may be Contour Trench, Staggered Trench, Crescent Bund, Boulder Bund or Pebble Bunds are formed in the field.

9.1.3 Treatment of Natural Water Course/ Drainage Lines

- a) The cadastral map has to be updated as regards the network of drainage lines (gullies/nalas/hallas) and existing structures are marked to the scale and storage capacity of the existing water bodies are documented.
- b) The drainage line will be demarcated into Upper Reach, Middle Reach and Lower Reach.
- c) Considering the Catchment, *Nala* bed and bank conditions, suitable structures are decided.
- d) Number of storage structures (Check dam/ *Nala* bund/ Percolation tank) will be decided considering the commitments and available runoff in water budgeting and quality of water in the wells and site suitability.
- e) Detailed Levelling Survey using Dumpy Level / Total Station has to be carried out to arrive at the site-specific designs as shown in the Manual.
- f) The location of ground water recharge structures are decided by examining the lineaments and fracture zones from geological maps.
- g) Rainfall intensity data of the nearest Rain gauge station is considered for Hydrologic Designs.
- h) Silt load to the Storage/Recharge structures is reduced by providing vegetative, boulder and earthern checks in the natural water course. Location and design details are given in the Manual.

9.2 Recommended Soil and Water Conservation Measures

The appropriate conservation structures best suited for each of the land parcel/ survey number (Appendix-I) are selected based on the slope per cent, severity of erosion, amount of rainfall, land use and soil type. The different kinds of conservation structures recommended are

- 1. Graded / Strengthening of Bunds
- 2. Trench cum Bunds (TCB)
- 3. Trench cum Bunds / Strengthening
- 4. Crescent Bunds

A map (Fig. 9.1) showing soil and water conservation plan with different kinds of structures recommended has been prepared which shows the spatial distribution and extent of area. Entire area needs graded bunding. The conservation plan prepared may be presented to all the stakeholders including farmers and after considering their suggestions, the conservation plan for the microwatershed may be finalised in a participatory approach.

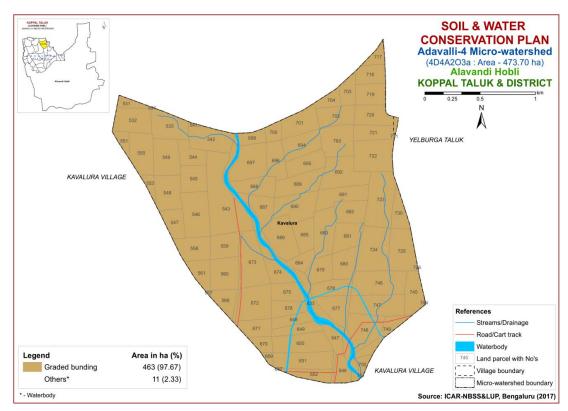

Fig. 9.1 Soil and Water Conservation Plan map of Adavalli-4 Microwatershed

9.3 Greening of Microwatershed

As part of the greening programme in the watersheds, it is envisaged to plant a variety of horticultural and other tree plants that are edible, economical and produce lot of biomass which helps to restore the ecological balance in the watersheds. The lands that are suitable for greening programme are non-arable lands (land capability Classes (V, VI VII and VIII) and also the lands that are not suitable or marginally suitable for growing annual and perennial crops. The method of planting these trees is given below.

It is recommended to open the pits during the 1st week of March along the contour and heap the dug out soil on the lower side of the slope in order to harness the flowing water and facilitate weathering of soil in the pit. Exposure of soil in the pit also prevents spread of pests and diseases due to scorching sun rays. The pits should be filled with mixture of soil and organic manure during the second week of April and keep ready with sufficiently tall seedlings produced either in poly bags or in root trainer nurseries so that planting can be done during the 2nd or 3rd week of April depending on the rainfall.

The tree species suitable for the area considering rainfall, temperature and adaptability is listed below; waterlogged areas are recommended to be planted with species like Neral (*Sizyzium cumini*) and Bamboo. Dry areas are to be planted with species like *Honge*, *Bevu*, *Seetaphal etc*.

	Dry De	eciduous Species	Temp (°C)	Rainfall (mm)
1.	Bevu	Azadiracta indica	21–32	400 –1,200
2.	Tapasi	Holoptelia integrifolia	20-30	500 - 1000
3.	Seetaphal	Anona Squamosa	20-40	400 - 1000
4.	Honge	Pongamia pinnata	20 -50	500-2,500
5.	Kamara	Hardwikia binata	25 -35	400 - 1000
6.	Bage	Albezzia lebbek	20 - 45	500 - 1000
7.	Ficus	Ficus bengalensis	20 - 50	500-2,500
8.	Sisso	Dalbargia Sissoo	20 - 50	500 -2000
9.	Ailanthus	Ailanthus excelsa	20 - 50	500 - 1000
10.	Hale	Wrightia tinctoria	25 - 45	500 - 1000
11.	Uded	Steriospermum chelanoides	25 - 45	500 -2000
12.	Dhupa	Boswella Serrata	20 - 40	500 - 2000
13.	Nelli	Emblica Officinalis	20 - 50	500 -1500
14.	Honne	Pterocarpus marsupium	20 - 40	500 - 2000
	Moist D	Deciduous Species	Temp (°C)	Rainfall (mm)
15.	Teak	Tectona grandis	20 - 50	500-5000
16.	Nandi	Legarstroemia lanceolata	20 - 40	500 - 4000
17.	Honne	Pterocarpus marsupium	20 - 40	500 - 3000
18.	Mathi	Terminalia alata	20 -50	500 - 2000
19.	Shivane	Gmelina arboria	20 -50	500 -2000
20.	Kindal	T.Paniculata	20 - 40	500 - 1500
21.	Beete	Dalbargia latifolia	20 - 40	500 - 1500
22.	Tare	T. belerica	20 - 40	500 - 2000
23.	Bamboo	Bambusa arundinasia	20 - 40	500 - 2500
24.	Bamboo	Dendrocalamus strictus	20 - 40	500 – 2500
25.	Muthuga	Butea monosperma	20 - 40	400 - 1500
26.	Hippe	Madhuca latifolia	20 - 40	500 - 2000
27.	Sandal	Santalum album	20 - 50	400 - 1000
28.	Nelli	Emblica officinalis	20 - 40	500 - 2000
29.	Nerale	Sizyzium cumini	20 - 40	500 - 2000
30.	Dhaman	Grevia tilifolia	20 - 40	500 - 2000
31.	Kaval	Careya arborea	20 - 40	500 - 2000
32.	Harada	Terminalia chebula	20 - 40	500 - 2000

EXECUTIVE SUMMARY

Baseline socioeconomic characterisation is prerequisite to prepare action plan for program implementation and to assess the project performance before making any changes in the watershed development program. The baseline provides appropriate policy direction for enhancing productivity and sustainability in agriculture.

Methodology: The Adavalli-4 micro-watershed (Koppal taluk and district) is located in between 15°19′ – 15°21′ North latitudes and 75°55′ – 75°57′ East longitudes, covering an area of about 473.70 ha, bounded by Kavalura village and Yelburga taluk. It falls under Agro Ecological Region (AER)–3: (Deccan plateau, hot arid ecosubregion) Karnataka Plateau (Rayalseema as inclusion), hot arid ESR with deep loamy and clayey mixed red and black soils, low to medium AWC and LGP 60-90 days We used soil resource map as basis for sampling farm households to test the hypothesis that soil quality influence crop selection, and conservation investment of farm households. The level of technology adoption and productivity gaps and livelihood patterns were analyses. The cost of soil degradation and ecosystem services were quantified for each watershed.

Results: We found that

Social Indicators;

- ❖ *Male and female ratio is 51 to 49 per cent to the total sample population*
- ❖ Younger age groups of population is around 64 per cent to the total population
- **&** *Literacy population is around 75per cent*
- ❖ Wood is the source of energy for a cooking among 89 per cent.
- ❖ Around 33 % of farmers have taken yeshaswini health cards
- Majority of farm households (89 %) are having MGNREGA card for rural employments
- ❖ Dependence on ration cards through public distribution system is around 89 per cent
- Swach bharath program providing closed toilet facilities around 11 per cent of sample households.
- ❖ *Institutional participation is only 14 per cent of sample households.*
- ❖ Women participation is decision making is found.

Economic Indicators;

- ❖ The average land holding is 2.47 ha indicates that majority of farm households are belong to marginal and small farmers.
- Agriculture is the main occupation only among 32 per cent and agricultural labours is predominant subsidiary occupation for 59 per cent of sample households.

- * The average value of domestic assets is around Rs 8091 per household. Mobile and television are mass popular mass communication media.
- ❖ The average farm assets values is around 5 lakhs, about 11 per cent of sample farmers are owing tractors.
- * The average livestock values are around Rs 16917 per livestock. The average milk produced is 1680 litter per lactation per animal.
- * The average fodder availability is 1044 kg/ha on season for the livestock feeding.
- * The average per capita food consumption is around 584 grams (1628.7 kilo calories) against national institute of nutrition recommendation at 827 gram. Around 100 per cent of sample farmers are consuming less than the NIN recommendation.
- * The annual average income is around Rs 98238 per household. About 56 per cent of farm households are below poverty line.
- ❖ The per capita monthly expenditure is around Rs 715 per household.

Environmental Indicators-Ecosystem services;

- ❖ The value of ecosystem service helps to support investment to decision on soil and water conservation and in promoting sustainable land use.
- ❖ The onsite cost of different soil nutrients lost due to soil erosion is around Rs 7004 per ha/year. The total cost of annual soil nutrients is around Rs 3309315 per year for the total area of 473.7 ha.
- ❖ The average value of ecosystem service for food production is around Rs 10177/ ha/year. Per ha food production services is maximum in Red gram (Rs 26171/ha) followed by Sorghum (Rs 13486/ha), Green gram (Rs. 9269/ha), sunflower (Rs. 8763), Bengal gram (Rs. 2578) and Maize (Rs. 1525).
- ❖ The average value of ecosystem service for fodder production is around Rs 1805/ ha/year. Per ha a fodder production service is maximum in maize (Rs 2947) and followed by Sorghum (Rs. 663)
- ❖ The data on water requirement for producing one quintal of grain is considered for estimating the total value of water required for crop production. The per hectare value of water used and value of water was maximum in Red gram (Rs 67233) followed by green gram (Rs 51173), bengal gram (Rs 45488), sorghum (Rs. 36719), sunflower (Rs 26257) and maize (Rs 998).

Economic Land Evaluation;

- ❖ The major cropping pattern is sunflower (29.97 %) followed by sorghum (20.64 %), Bengal gram (20.44 %), green gram (15.33 %), Maize (8.51 %) and red gram (5.11 %).
- ❖ In Adavalli-4 Microwatershed, soil major soil series is Muttal (MTL) soil series are having shallow soil depth cover around 22 per cent of area. On this soil farmers are presently growing is sunflower. Handrala (HDL) soil series are

having deep soil depth cover around 7 per cent of area, major crop grown are bengal gram (50 %), Red gram (25 %) and Green gram (25 %). Bardur (BDR) soil series are very deep soil depth cover around 18 per cent area, crop grown are maize (53 %) and Sunflower (47 %). Narasapura (NSP) and Dambarahalli (DRL) soils series moderately deep soil depth cover around 27 % and 14 % of area respectively. The major crop grown is Sorghum, Sunflower, Bengal gram and Green gram.

- ❖ The total cost of cultivation in study area for sunflower ranges between Rs. 21372/ha in MTL soil (with BCR of 1.69) and Rs. 12514/ha in DRL soil (with BCR of 1.11).
- ❖ In green gram the cost of cultivation range between Rs. 27561/ha in HDL soils (with BCR of 1.08) and Rs. 19249/ ha in NSP soil (with BCR of 1.62).
- ❖ In bengal gram the cost of cultivation range between Rs. 30120/ha in HDL soil (with BCR of 1.03) and Rs. 23566 /ha in NSP soils (with BCR of 1.03).
- ❖ In sorghum the cost of cultivation range between Rs Rs. 14565/ha in DRL soils is (with BCR of 1.66) and Rs. 11171/ha in HDL soils (with BCR of 1.7).
- ❖ In red gram the cost of cultivation in HDL soil is Rs 19857/ha (with BCR of 2.24) and maize cultivation in BDR soils of Rs. 17224/ha with BCR of (1.13).

Suggestions;

- ❖ Involving farmers is watershed planning helps in strengthing institutional participation.
- ❖ The per capita food consumption and monthly income is very low. Diversifying income generation activities from crop and livestock production in order to reduce risk related to drought and market prices.
- * Majority of farmers reported that they are not getting timely support/extension services from the concerned development departments.
- ❖ By strengthing agricultural extension for providing timely advice improved technology there is scope to increase in net income of farm households.
- ❖ By adopting recommended package of practices by following the soil test fertiliser recommendation, there is scope to increase yield in Sunflower (8.9 %), bengal gram (16.7 to 35. %), maize (85.6 %), red gram (9.1 %), sorghum (20 to 50.5 %) and sunflower (44.4 to 57.1 %).

INTRODUCTION

Sujala is a Watershed Development Project conceptualised by the Government of Karnataka and implemented by the Watershed Development Department of Government of Karnataka with tripartite cost-sharing arrangements. The World Bank through International Development Association provided major portion of plan outlay as a loan to Government of India and in turn loan to Government of Karnataka.

The Project Development Objective of Sujala-III is to demonstrate more effective watershed management through greater integration of programs related to rainfed agriculture, innovative and science based approaches and strengthened institutions and capacities. The project is implemented in 11 districts of Bidar, Vijayapura, Gulbarga, Yadgiri, Koppal, Gadag, Raichur, Davanagere, Tumkur, Chikkamangalur and Chamarajanagar which have been identified by the Watershed Development Department based on rainfall water and socio-economic conditions. The project will be implemented over six years and linked with the centrally financed IWMP.

The present study aims to characterize socio-economic status of farm households, assess the land and water use status, evaluate the economic viability of land use and prioritize farming constraints and suggest the measures for soil and water conservation for sustainable agriculture.

Objectives of the study

- 1. To characterize socio-economic status of farm households
- 2. To evaluate the economic viability of land use and land related constraints
- 3. To estimate the ecosystem service provided by the watershed and
- 4. To suggest alternatives for sustainable agriculture production.

METHODOLOGY

Study area

Agro-climatic Zone 3: Northern Dry Zone: This zone is the largest in the state with a geographical area of 5.04 M ha, of which about 3.55 M ha is under cultivation. Irrigation is available to about 0.49 M ha. The zone encompasses the entire districts of Bijapur and Bellary, 6 taluks of Koppal, 5 taluks of Dharwad and 5 taluks of Belgaum. Of the 35 taluks in the zone, 9 taluks have a mean elevation of 800-900 m MSL while the rest have an elevation of 450-800 m. The rainfall is similar to that of the northeastern dry zone, ranging between 465 and 785 mm. Black soils are predominant in the zone with depth ranging from shallow to deep. General cropping season is *kharif* in shallow black soils and *rabi* in medium and deep black soils. Important crops are jowar, maize, bajra, groundnut, pulses, sunflower, cotton and sugarcane.

The Adavalli-4 micro-watershed (Koppal taluk and district) is located in between 15⁰19' – 15⁰21' North latitudes and 75⁰55' – 75⁰57' East longitudes, covering an area of about 473.70 ha, bounded by Kavalura village and Yelburga taluk. It falls under **Agro Ecological Region (AER)–3: (Deccan plateau, hot arid ecosubregion)** Karnataka Plateau (Rayalseema as inclusion), hot arid ESR with deep loamy and clayey mixed red and black soils, low to medium AWC and LGP 60-90 days (Figure 1).

Sampling Procedure:

In this study we have followed soil variability as criterion for sampling the farm households. In each micro-watershed the survey numbers and associated soil series are listed. Minimum three farm households for each soil series were taken and summed up to arrive at total sample for analysis.

Sources of data and analysis:

For evaluating the specific objectives of the study, primary data was collected from the sample respondents by personal interview method with the help of pre-tested questionnaire. The data on socio-economic characteristics of respondents such as family size and composition, land holdings, asset position, occupational pattern and education level was collected. The present cropping pattern and the level of input use and yields collected during survry. The data collected from the representative farm households were analysed using Automated Land Potential Evalution System (Figure 2).

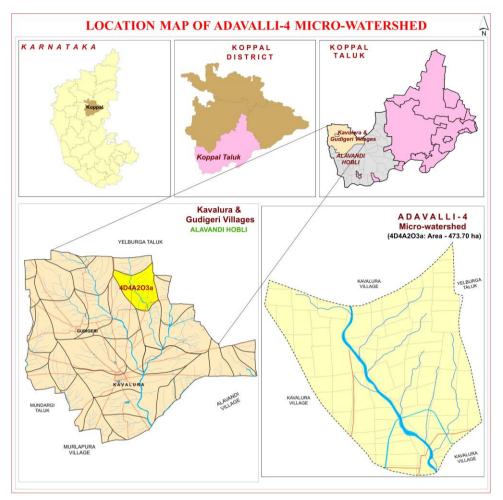

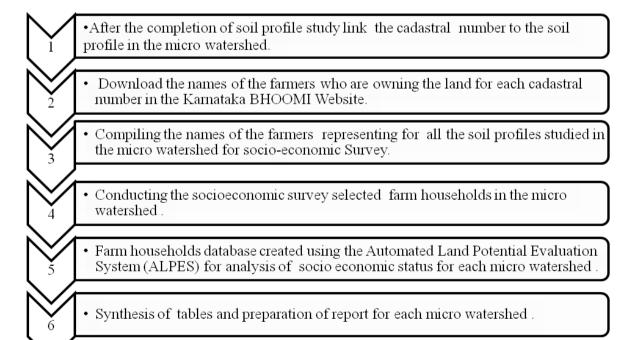

Figure 1: Location of study area

Steps followed in socio-economic assessment

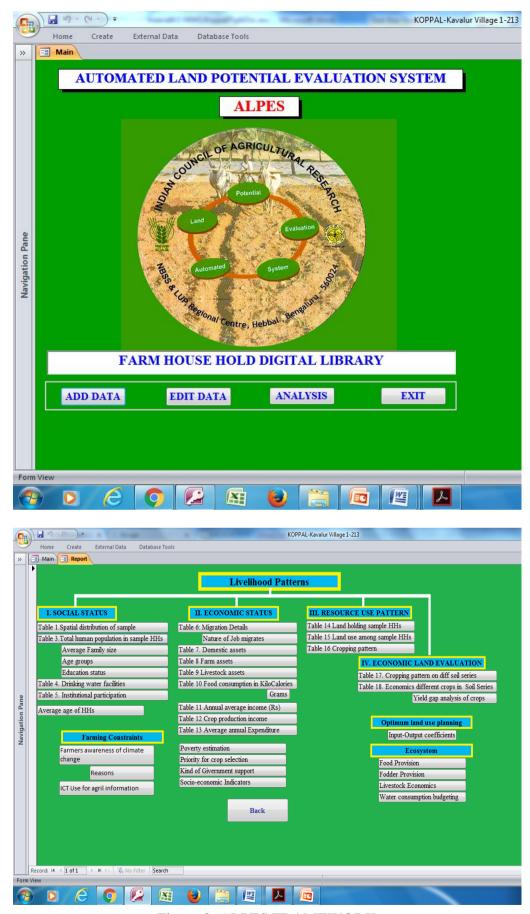

Figure 2: ALPES FRAMEWORK

The sample farmers were post classified in to marginal and small (0.00 to <=4.94 acres), medium and semi medium (>4.94 to <=24.7 acres) and large (>24.7 acres). The steps involved in estimation of soil potential involve estimation of total cost of cultivation, the yield/gross returns and net income per hectare. The cost of inputs such seed, manure and fertilizer, plant protection chemicals, payment towards human and bullock labour and interest on working capita are included under operational costs. In the case of perennial crops, the cost of establishment was estimated by using actual physical requirements and prevailing market prices. Estimation cost included maintenance cost up to bearing period. The value of main product and by product from the crop enterprise at the market rates were the gross returns of the crop. Net returns were worked out by deducting establishment and maintained cost from gross returns.

Operational Cost = cost of seeds, fertilizers, pesticides. Cost of human and bullock labour, cost of machinery, cost of irrigation water + interest on working capital.

Gross returns = Yield (Quintals/hectare)*Price (Rs/Quintal)

Net returns = Gross returns-Operational cost.

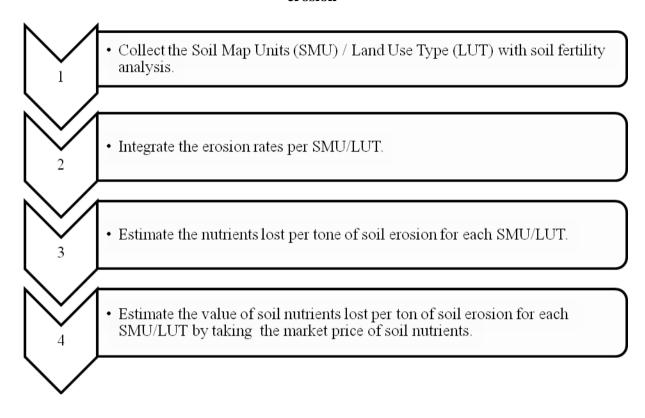

Benefit Cost Ratio = Net returns/Total cost.

Economic suitability classes: once each land use —land area combination has been assigned an economic value by the land evaluation, the question arises as to its 'suitability', that is, the degree to which it satisfies the land user. The FAO framework defines two suitability orders: 'S'(suitable if benefit cost ratio (BCR)>1) and 'N'(not suitable if (BCR<1), which are dived into five economic suitability classes: 'S1'(highly suitable if BCR>3), 'S2'(suitable if BCR>2 and <3), 'S3'(Marginally suitable if BCR>1 and <2), 'N1'(Not suitable for economic reasons but physically suitable) and 'N2'(not suitable for physical reasons). The limit between 'S3' and 'N1'must be at least at the point of financial feasibility (i.e. net returns, NPV, or IRR>0 and BCR>1). The other limits depend on social factors such as farm size, family size, alternative employment or investment possibilities and wealth expectations; these need to be specified for the Soil series.

Economic Valuation of Soil ecosystem services:

The replacement cost approach was followed for estimating the onsite cost of soil erosion, Market price method was followed for estimating the value of food and fodder production. Value transfer menthods was followed for estimating the value of water demand by different crops in the micro watershed.

Steps followed in Replacement cost methods for estimation of onsite cost of soil erosion

RESULTS AND DISCUSSIONS

The main purpose to characterise the socio-economic systems in the watershed is to identify the existing production constraints and propose the potential/alternate options for agro-technology transfer and for bridging the adoption and yield gap. The demographic information shows that the household population dynamics encompasses the socioeconomic status of the farmer. For a rural family, the household size should be optimal to earn a comfortable livelihood through farm and non-farm wage earning. The total number of population in the watershed area was 28, out of which 51.4 per cent were males, 48.4 per cent female. Average family size of the households is 3.1. Age is an important factor, which affects the potential employment and mobility status of respondents. The data on age wise distribution of farmers in the sample households indicated that majority of the farmers are coming under the age group of 30 to 50 years (39.3 %) followed by 18 to 30 years (25 %), more than 50 years (17.9 %) and 0 to 18 years (17.9 %). Hence, in the study area in general, the respondents were of young and middle age, indicating thereby that the households had almost settled with whatever livelihood options they were practicing and sample respondents were young by age who could venture into various options of livelihood sources. Data on literacy indicated that 25 per cent of respondents were illiterate and 75 per cent literate (Table 1).

Table 1: Human population among sample households in Adavalli-4 Microwatershed

Particulars	Units	Values

The ethnic groups among the sample farm households found 11 per cent are belong to Other Backward Castes (OBC) and others are general castes (Table 2 and

Figure 3). About 88.9 per cent of sample households are using fire wood as source of fuel for cooking. Majority of the farmers (88.9 %) are having electricity connection. About 33.3 per cent are sample households are having health cards. Majority (88.9 %) are having MNREGA job cards for employment generation. About 89 per cent of farm households are having ration cards for taking food grains from public distribution system. Only 11.1 per cent of farm households are having toilet facilities.

Table 2: Basic needs of sample households in Adavalli-4 Microwatershed

Television	77.8	2743	
Average value		8091	

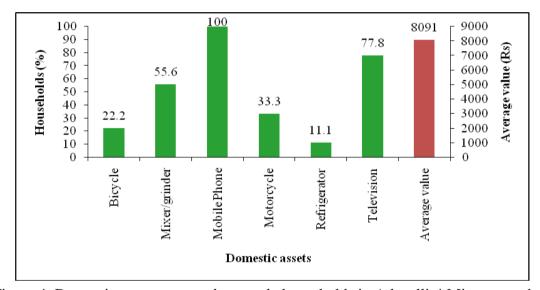

Figure 4: Domestic assets among the sample households in Adavalli-4 Microwatershed

The most popularly owned farm equipments were sickles, plough, cattle shed; pump sets, chaff cutter, bullock cart, sprayer and thresher. Plough and sickle were commonly present in all the sampled farmers; these were primary implements in agriculture. The per cent of households owned tractors (11 %), Harvesters (33.3 %), Sprayers (60 %), weeders (100 %) and earth removers (11.1 %) was found among the sample households (Table 6 and Figure 5).

Table 6: Farm assets among samples households in Adavalli-4 Microwatershed

Particulars	% of HHs	Average value in Rs
Earth Remover	11.1	15000
Harvester	33.3	60
Sprayer	11.1	1500
Tractor	11.1	250000
Weeder	100.0	70
Average value	53326	

Livestock is an integral component of the conventional farming systems (Table 7). The majority of livestock population are local dry cows, local milching cows, crossbred

dry cows, crossbred milching cows, dry buffalos and bullocks are found among the sample households. The average livestock value was Rs 16917 per livestock.

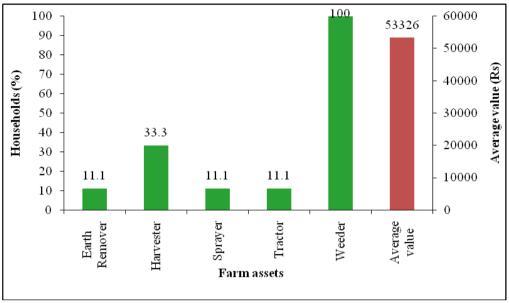

Figure 5: Farm assets among samples households in Adavalli-4 Microwatershed

The food intake in terms of kilo calorie (kcal) per person per day was calculated and presented in Table 10 and Figure 6. More quantity of cereals are consumed by sample farmers which accounted for 1249.2 kcal per person. The other important food items consumed was pulses 112.6 kcal followed by cooking oil 195.6 kcal, milk 56 kcal and vegetables 15.3 kcal. In the sampled households, farmers were consuming less (1628.7 kcal) than NIN- recommended food requirement (2250 kcal).

Table 10: Per capita daily consumption of food among the sample farmers in Adavalli-4 Microwatershed

Annual income of the sample HHs: The average annual household income is around Rs. 98238. Major source of income to the farmers in the study area is form livestock (Rs. 80890) followed by the crop production (Rs. 17348). The monthly per capita income is Rs. 2770 which is more than the threshold monthly income of Rs. 975 for considering above poverty line. Due to the fact that erratic rainfall and shortage of water, farmers are diverting from crop production activities to enable the household for a comfortable livelihood. The incomes from the other aforesaid sources are very meagre (Table 11).

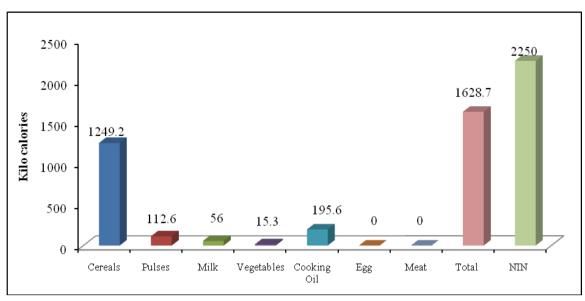

Figure 6: Per capita daily consumption of food among the sample farmers

The average annual expenditure of farm households indicated that farmers in the study area spend highest on food (Rs. 22080) followed by education, clothing, social function and health. Now a days education is most important among all of us. In today's competitive world, education is a necessity for man after food, clothing, and shelter. It is the only fundamental way by which a desired change in the society can happen. The average per capita monthly expenditure is around Rs 715 and about 44.4 per cent of farm households are below poverty line and 55.6 per of farm households are above poverty line (Table 12 and Figure 7).

Table 12: Average annual expenditure of sample HHs in Adavalli-4 Microwatershed

Economic land evaluation

In Adavalli-4 micro-watershed 8 soil series are identified and mapped (Table 16). The distribution of major soil series are Narasapura soils covering an area of 129 ha (27.23 %) followed by Muttal 103 ha (21.76 %), Bardur 86 ha (18.24 %), Dambarahalli 65 ha (13.77 %), Handral 35 ha (7.38 %), Ravanaki 27 ha (5.56 %), and Kadagathur 17 ha (3.68 %) and Belagatti 0.22 ha (0.05 %).

Table 16: Distribution of soil series in Adavalli-4 Microwatershed

Sl. No	Soil series	Area in ha (%)
1	Belagatti (BGT)	0.22 (0.05)
2	Bardur (BDR)	86 (18.24)
3	Dambarahalli (DRL)	65 (13.77)
4	Handrala (HDL)	35 (7.38)
5	Kadagathur (KDT)	17 (3.68)
6	Muttal (MTL)	103 (21.76)
7	Narasapura (NSP)	129 (27.23)
8	Ravanaki (RNK)	27 (5.56)
	Others	11 (2.33)
	Total	473.7

Present cropping pattern on different soil series are given in Table 17. Crop grown on Muttal soils is Sunflower. Sorghum and sunflower on Dambarahalli soils. Bengal gram, green gram and sorghum on Narasapura soils, Bengal gram, green gram and red gram on Handral soils and maize and sunflower on Bardur soils.

Table 17: Cropping pattern on major soil series in Adavalli-4 micro-watershed

(Area in per cent)

Soil Series	Coil Donth	Chang	Dı	y	Grand Total	
Son Series	Soil Depth	Crops	Kharif	Rabi	Grand Total

Green gram range between Rs. 27561/ha in HDL soils (with BCR of 1.08) and Rs. 19249/ha in NSP soil (with BCR of 1.62), Bengal gram range between Rs. 30120/ha in HDL soil (with BCR of 1.03) and Rs. 23566 /ha in NSP soils (with BCR of 1.03), sorghum range between Rs Rs. 14565/ha in DRL soils is (with BCR of 1.66) and Rs. 11171/ha in HDL soils (with BCR of 1.7), Red gram cultivation in HDL soil is Rs 19857/ha (with BCR of 2.24) and Maize cultivation in BDR soils of Rs. 17224/ha with BCR of (1.13).

The data on FYM, Nitrogen, Phosphorus and Potash application by the farmers to different crops and recommended FYM for different crops is given in Table 19. There is a huge gap between FYM application by farmers and recommended FYM in all the crops across the soils. There is a larger Yield gap in crops grown across different soil series. Adequate knowledge about recommended package of practices is the pre-requisite for their use in cultivation of crops. It is a fact that, recommended practices are major contributing factors to yield. Inadequate knowledge about recommended practices leads to their improper adoption. Strengthening of extension services by concerned agency is required to increase adoption of recommended cultivation practices and ultimately reducing the gap. By adopting soil-test fertiliser recommendation, there is scope to increase yield and income to a maximum of Rs 92164 in Maize and a minimum of Rs 713 in sunflower cultivation.

Economic valuation of Ecosystem Services (ES) was aimed at combining use and non-use values to determine Total Economic Value (TEV) of ES. Ecosystem Services (ES) were valued based on their annual flow or utilization in common monetary units, Rs/year. The valuation of ES was based on market price in 2017 or market cost approaches whichever is applicable, and in other cases on value or benefit transfer from previous valuation studies.

The onsite cost of different soil nutrients lost due to soil erosion is given in Table 20 and Figure 9. The average value of soil nutrient loss is around Rs 7004 per ha/year. The total cost of annual soil nutrients is around Rs 3309315 per year for the total area of 473.7 ha.

Table 20: Estimation of onsite cost of soil erosion in Adavalli-4 micro-watershed

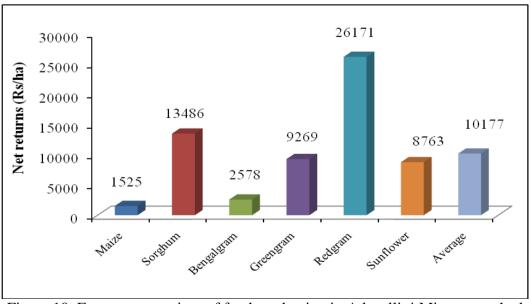

Figure 10: Ecosystem services of food production in Adavalli-4 Microwatershed

The average value of ecosystem service for fodder production is around Rs 1805/ha/year (Table 22). Per ha a fodder production service is highest in maize (Rs 2947) and followed by Sorghum (Rs. 663).

Table 22: Ecosystem services of fodder production in Adavalli-4 Microwatershed

Production	Crong	Area	Yield	Price	Returns	Total returns
items	Crops	in ha	(Qtl/ha)	(Rs/Qtl)	(Rs/ha)	(Rs)
Cereals	Maize	3.34	1.25	2350	2947	9843
	Sorghum	4.91	0.66	1000	663	3252
Grand total		8.25	0.96	1675	1805	6548

The water demand for production of different crops was worked out in arriving at the ecosystem services of water support to crop growth. The data on water requirement for producing one quintal of grain is considered for estimating the total value of water required for crop production. The per hectare value of water used and value of water was maximum (Table 23 and Figure 11) in Red gram (Rs 67233) followed by green gram (Rs 51173), bengal gram (Rs 45488), sorghum (Rs. 36719), sunflower (Rs 26257) and Maize (Rs 998).

Table 23: Ecosystem services of water supply in Adavalli-4 Microwatershed

Crops	Yield (Qtl/ha)	Virtual water (cubic meter) per ha	Value of Water (Rs/ha)	Water consumption (Cubic meters/Qtl)
Bengal gram	6.59	4549	45488	691
Green gram	7.41	5117	51173	691
Maize	8.17	998	9984	122
Red gram	12.35	6723	67233	544
Sorghum	12.05	3672	36719	305
Sunflower	7.80	2626	26257	337
Grand Total	8.86	3541	35408	400

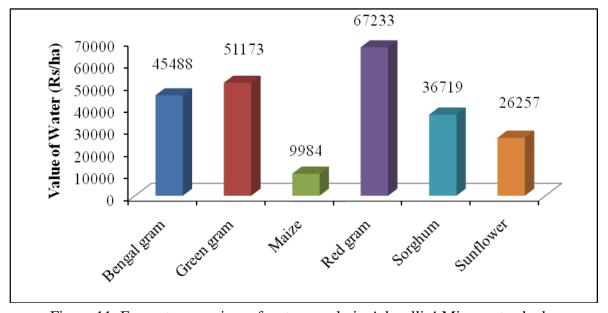

Figure 11: Ecosystem services of water supply in Adavalli-4 Microwatershed

The main constraints in farming is climate change particularly decline in rainfall and increasing temperature. Farmers reported that they are not getting timely support/extension services from the concerned development departments (Table 23).

Table 24: Farming constraints related land resources of sample households in Adavalli-4 Microwatershed

Particulars	Per cent				
Farmers awareness of climate change					
Yes	10				
No	90				
Perception on climate change					
Decrease in rainfall	100				
Increase in temperature	0				
Availability agricultural technology information					
Yes	0				
No	100				

The findings of the study would be very much useful to the planners and policy makers of the study area to identify the irrationality in the existing production pattern and to suggest appropriate production plans for efficient utilization of their scarce resources resulting in increased net farm incomes and employment. The study also throws light on future potentialities of increasing net farm income and employment under different situations viz., with existing and recommended technology.
