Tetra-allele cross is often referred as four-way cross or double cross or four-line cross are those type of mating designs in which every cross is obtained by mating amongst four inbred lines. A tetra-allele cross can be obtained by crossing the resultant of two unrelated diallel crosses. A common triallell cross involving four inbred lines A, B, C and D can be symbolically represented as \((A\times B)\times(C\times D)\) or \((A, B, C, D)\) etc. Tetra-allele cross can be broadly categorized as Complete Tetra-allele Cross (CT\(_{aC}\)) and Partial Tetra-allele Crosses (PT\(_{aC}\)).

Rawlings and Cockerham (1962) firstly introduced and gave the method of analysis for tetra-allele cross hybrids using the analysis method of single cross hybrids under the assumption of no linkage.

The set of all possible four-way mating between several genotypes (individuals, clones, homozygous lines, etc.) leads to a CT\(_{aC}\). If there are \(N\) number of inbred lines involved in a CT\(_{aC}\), the the total number of crosses, \(T = \frac{N(N-1)(N-2)(N-3)}{8}\). Here is an example of complete tetra-allele cross consisting of 15 crosses that can be made for 5 lines (1, 2, 3, 4 and 5).

\[
\begin{array}{cccc}
(1\times2)\times(3\times4) & (1\times3)\times(4\times5) & (1\times4)\times(2\times5) & (1\times5)\times(3\times4) \\
(1\times2)\times(3\times5) & (1\times3)\times(2\times5) & (1\times4)\times(3\times5) & (1\times5)\times(2\times3) \\
(1\times2)\times(4\times5) & (1\times3)\times(2\times4) & (1\times4)\times(2\times3) & (1\times5)\times(2\times4) \\
& (2\times4)\times(3\times5) & & \\
\end{array}
\]

When more number of lines are to be considered, the total number of crosses in CT\(_{aC}\) also increases. Thus, it is almost impossible for the investigator to carry out the experimentation with limited available resource material. This situation lies in taking a fraction of CT\(_{aC}\) with certain underlying properties, known as PT\(_{aC}\). Here, a SAS macro has been developed to generate a series of universally optimal family of designs using MOLS. The method starts with selecting any of the \(\frac{(N-1)}{2}\) MOLS of a given order \(N\) (the number of lines) and retaining the first four rows and making crosses with the lines.
occurring in each column. The parameters of the developed class of design is $T = \frac{N(N-1)}{2}$, $b = \frac{(N-1)}{2}$, $r, k = N$ and $f = \frac{4}{(N-2)(N-3)}$.

**Example:** For $N = 7$, considering 3 MOLS of order 7 chosen at random out of the total 6 possible MOLS of order 7, and retaining only first 4 rows of each, based on the symbols 1, 2, 3, 4, 5, 6 and 7 as given below.

<table>
<thead>
<tr>
<th>MOLS I</th>
<th>MOLS II</th>
<th>MOLS III</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3 4 5 6 7</td>
<td>1 2 3 4 5 6 7</td>
<td>1 2 3 4 5 6 7</td>
</tr>
<tr>
<td>2 3 4 5 6 7 1</td>
<td>3 4 5 6 7 1 2</td>
<td>4 5 6 7 1 2 3</td>
</tr>
<tr>
<td>3 4 5 6 7 1 2</td>
<td>5 6 7 1 2 3 4</td>
<td>7 1 2 3 4 5 6</td>
</tr>
<tr>
<td>4 5 6 7 1 2 3</td>
<td>7 1 2 3 4 5 6</td>
<td>3 4 5 6 7 1 2</td>
</tr>
</tbody>
</table>

Now, considering the seven symbols as lines, from each LS a tetra-allele crosses can be made by taking the four lines of each column. The crosses made from each LS will be constituting a block.

The layout of the design can be obtained as generated using the developed SAS macro by just entering the number of lines.
